Chapter 1

Getting Started

Topics:

- Zowe overview
- Zowe architecture
- Release notes
- Zowe CLI quick start
- Frequently Asked Questions
- Zowe resources
Zowe overview

Zowe™ is an open source project created to host technologies that benefit the IBM Z platform for all members of the Z community, including Integrated Software Vendors (ISVs), System Integrators, and z/OS consumers. Zowe, like Mac or Windows, comes with a set of APIs and OS capabilities that applications build on and also includes some applications out of the box. Zowe offers modern interfaces to interact with z/OS and allows you to work with z/OS in a way that is similar to what you experience on cloud platforms today. You can use these interfaces as delivered or through plug-ins and extensions that are created by clients or third-party vendors.

Zowe Demo Video

Watch this video to see a quick demo of Zowe.

Component Overview

Zowe consists of the following components:

Zowe Application Framework

A web user interface (UI) that provides a virtual desktop containing a number of apps allowing access to z/OS function. Base Zowe includes apps for traditional access such as a 3270 terminal and a VT Terminal, as well as an editor and explorers for working with JES, MVS Data Sets and Unix System Services.

Learn more

The Zowe Application Framework modernizes and simplifies working on the mainframe. With the Zowe Application Framework, you can create applications to suit your specific needs. The Zowe Application Framework contains a web UI that has the following features:

• The web UI works with the underlying REST APIs for data, jobs, and subsystem, but presents the information in a full screen mode as compared to the command line interface.
• The web UI makes use of leading-edge web presentation technology and is also extensible through web UI plug-ins to capture and present a wide variety of information.
• The web UI facilitates common z/OS developer or system programmer tasks by providing an editor for common text-based files like REXX or JCL along with general purpose data set actions for both Unix System Services (USS) and Partitioned Data Sets (PDS) plus Job Entry System (JES) logs.

The Zowe Application Framework consists of the following components:

• Zowe Desktop

The desktop, accessed through a browser. The desktop contains a number of applications, including a TN3270 emulator for traditional Telnet or TLS terminal access to z/OS, a VT Terminal for SSH commands, as well as rich web GUI applications including a JES Explorer for working with jobs and spool output, a File Editor for working with USS directories and files and MVS data sets and members. The Zowe desktop is extensible and allows vendors to provide their own applications to run within the desktop. See Overview on page 242. The
following screen capture of a Zowe desktop shows some of its composition as well as the TN3270 app, the JES Explorer, and the File Editor open and in use.

- **Zowe Application Server**
  The Zowe Application Server runs the Zowe Application Framework. It consists of the Node.js server plus the Express.js as a webservice framework, and the proxy applications that communicate with the z/OS services and components.

- **ZSS Server**
  The ZSS Server provides secure REST services to support the Zowe Application Server. For services that need to run as APF authorized code, Zowe uses an angel process that the ZSS Server calls using cross memory.
communication. During installation and configuration of Zowe, you will see the steps needed to configure and launch the cross memory server.

- **Application plug-ins**
  Several application-type plug-ins are provided. For more information, see Zowe Desktop application plug-ins on page 162.

**z/OS Services**
Provides a range of APIs for the management of z/OS JES jobs and MVS data set services.

- **z/OS Datasets services**
  Get a list of data sets, retrieve content from a member, create a data set, and more.

- **z/OS Jobs services**
  Get a list of jobs, get content from a job file output, submit a job from a data set, and more.

You can view the full list of capabilities of the RESTful APIs from the API catalog that displays the Open API Specification for their capabilities.

- These APIs are described by the Open API Specification allowing them to be incorporated to any standard-based REST API developer tool or API management process.
- These APIs can be exploited by off-platform applications with proper security controls.

As a deployment architecture, the z/OS Services are running as microservices with a Springboot embedded Tomcat stack.

**Zowe CLI**
Zowe CLI is a command-line interface that lets you interact with the mainframe in a familiar, off-platform format. Zowe CLI helps to increase overall productivity, reduce the learning curve for developing mainframe applications, and exploit the ease-of-use of off-platform tools. Zowe CLI lets you use common tools such as Integrated Development Environments (IDEs), shell commands, bash scripts, and build tools for mainframe development. Though its ecosystem of plug-ins, you can automate actions on systems such as IBM Db2, IBM CICS, and more. It provides a set of utilities and services for users that want to become efficient in supporting and building z/OS applications quickly.

- **Interact with mainframe files:** Create, edit, download, and upload mainframe files (data sets) directly from Zowe CLI.
- **Submit jobs:** Submit JCL from data sets or local storage, monitor the status, and view and download the output automatically.
• **Issue TSO and z/OS console commands:** Issue TSO and console commands to the mainframe directly from Zowe CLI.

• **Integrate z/OS actions into scripts:** Build local scripts that accomplish both mainframe and local tasks.

• **Produce responses as JSON documents:** Return data in JSON format on request for consumption in other programming languages.

For detailed information about the available functionality in Zowe CLI, see [Zowe CLI command groups](#) on page 176.

For information about extending the functionality of Zowe CLI by installing plug-ins, see [Extending Zowe CLI](#) on page 180.

**More Information:**

• [System requirements](#) on page 48

• [Installing Zowe CLI](#) on page 116

**API Mediation Layer**

Provides a gateway that acts as a reverse proxy for z/OS services, together with a catalog of REST APIs and a dynamic discovery capability. Base Zowe provides core services for working with MVS Data Sets, JES, as well as working with z/OSMF REST APIs. The API Mediation Layer also provides a framework for Single Sign On (SSO).

Learn more

The API Mediation Layer provides a single point of access for mainframe service REST APIs. The layer offers enterprise, cloud-like features such as high-availability, scalability, dynamic API discovery, consistent security, a single sign-on experience, and documentation. The API Mediation Layer facilitates secure communication across loosely coupled microservices through the API Gateway. The API Mediation Layer consists of three components: the Gateway, the Discovery Service, and the Catalog. The Gateway provides secure communication across loosely coupled API services. The Discovery Service enables you to determine the location and status of service instances running inside the API ML ecosystem. The Catalog provides an easy-to-use interface to view all discovered services, their associated APIs, and Swagger documentation in a user-friendly manner.

**Key features**

• Consistent Access: API routing and standardization of API service URLs through the Gateway component provides users with a consistent way to access mainframe APIs at a predefined address.

• Dynamic Discovery: The Discovery Service automatically determines the location and status of API services.

• High-Availability: API Mediation Layer is designed with high-availability of services and scalability in mind.

• Redundancy and Scalability: API service throughput is easily increased by starting multiple API service instances without the need to change configuration.

• Presentation of Services: The API Catalog component provides easy access to discovered API services and their associated documentation in a user-friendly manner. Access to the contents of the API Catalog is controlled through a z/OS security facility.

• Encrypted Communication: API ML facilitates secure and trusted communication across both internal components and discovered API services.

**API Mediation Layer architecture**

The following diagram illustrates the single point of access through the Gateway, and the interactions between API ML components and services:
Components

The API Layer consists of the following key components:

API Gateway

Services that comprise the API ML service ecosystem are located behind a gateway (reverse proxy). All end users and API client applications interact through the Gateway. Each service is assigned a unique service ID that is used in the access URL. Based on the service ID, the Gateway forwards incoming API requests to the appropriate service. Multiple Gateway instances can be started to achieve high-availability. The Gateway access URL remains unchanged. The Gateway is built using Netflix Zuul and Spring Boot technologies.
Discovery Service

The Discovery Service is the central repository of active services in the API ML ecosystem. The Discovery Service continuously collects and aggregates service information and serves as a repository of active services. When a service is started, it sends its metadata, such as the original URL, assigned serviceld, and status information to the Discovery Service. Back-end microservices register with this service either directly or by using a Eureka client. Multiple enablers are available to help with service on-boarding of various application architectures including plain Java applications and Java applications that use the Spring Boot framework. The Discovery Service is built on Eureka and Spring Boot technology.

Discovery Service TLS/SSL

HTTPS protocol can be enabled during API ML configuration and is highly recommended. Beyond encrypting communication, the HTTPS configuration for the Discovery Service enables heightened security for service registration. Without HTTPS, services provide a username and password to register in the API ML ecosystem. When using HTTPS, only trusted services that provide HTTPS certificates signed by a trusted certificate authority can be registered.

API Catalog

The API Catalog is the catalog of published API services and their associated documentation. The Catalog provides both the REST APIs and a web user interface (UI) to access them. The web UI follows the industry standard Swagger UI component to visualize API documentation in OpenAPI JSON format for each service. A service can be implemented by one or more service instances, which provide exactly the same service for high-availability or scalability.

Catalog Security

Access to the API Catalog can be protected with an Enterprise z/OS Security Manager such as IBM RACF, CA ACF2, or CA Top Secret. Only users who provide proper mainframe credentials can access the Catalog. Client authentication is implemented through the z/OSMF API.

Onboarding APIs

Essential to the API Mediation Layer ecosystem is the API services that expose their useful APIs. Use the following topics to discover more about adding new APIs to the API Mediation Layer and using the API Catalog:

- Onboarding Overview on page 211
- Onboard an existing Spring Boot REST API service using Zowe API Mediation Layer
- Using API Catalog on page 166

To learn more about the architecture of Zowe, see Zowe architecture.

Zowe Third-Party Software Requirements and Bill of Materials

- Third-Party Software Requirements (TPSR)
- Bill of Materials (BOM)

Zowe architecture

Zowe™ is a collection of components that together form a framework that allows Z-based functionality to be accessible across an organization. This includes exposing Z-based components such as z/OSMF as Rest APIs. The framework provides an environment where other components can be included and exposed to a broader non-Z based audience.

The following diagram depicts the high-level Zowe architecture.
The diagram shows the default port numbers that are used by Zowe. These are dependent on each instance of Zowe and are held in the Zowe instance directory configuration file `instance.env`. For more information, see Creating and configuring the Zowe instance directory on page 104.

A number of servers run under Unix System Services (USS) on z/OS. These run under the Zowe started task `ZWESVSTC` that has its own user ID `ZWESVUSR` and include a number of servers each with their own address space. The `ZWESVSTC` started task has a `STDOUT` file that includes log and trace information for its servers. Sever error messages are written to `STDERR` and for problem determination. See Troubleshooting on page 288.

**ZLUX**

The ZLUX Node.js server is also known as the Zowe Application Framework. It provides the Zowe desktop that you can access through a web browser via port 8544. The Zowe desktop includes a number of applications that run inside the ZLUX Zowe Application Framework including a 3270 emulator and a File Editor.
The ZLUX server logs are written to `<INSTANCE_DIR>/logs/appServer-yyyy-mm-dd-hh-mm.log`. The Zowe Application Framework provides REST APIs for its services that are included on the API catalog tile `Zowe Application Framework` that can be viewed at `https://<ZOWE_HOST_IP>:7554/ui/v1/apicatalog/#/tile/ZLUX/zlux`.

**zssServer**

The Zowe desktop delegates a number of its services to the zssServer which it accesses through the http port 8542. The zssServer is written in metalC and has native calls to z/OS to provide its services. The zssServer logs are written to `<INSTANCE_DIR>/logs/zssServer-yyyy-mm-dd-hh-mm.log`.

**API Gateway**

The API Gateway is a proxy server that routes requests from clients on its northbound edge, such as web browsers or the Zowe command line interface, to servers on its southbound edge that are able to provide data to serve the request. It is also responsible for generating the authentication token used to provide single sign-on (SSO) functionality. The API Gateway homepage is `https://<ZOWE_HOST_IP>:7554`, that after authentication allows you to navigate to the API Catalog.
API Catalog

The API Catalog provides a list of the API services that have registered themselves as catalog tiles. These allow you to view the available APIs from Zowe's southbound servers as well as test REST API calls.
API Discovery

The API Discovery server acts as the registration service broker between the API Gateway and its southbound servers. It can be accessed through the URL https://<ZOWE_HOST_IP>:7552. You can view a list of registered API services on the API discovery homepage.
MVS, JES, and USS UI

Zowe provides a number of rich GUI web applications for working with z/OS. This includes the MVS Explorer for data sets, the JES Explorer for jobs, and the USS Explorer for the Unix File System. You can access them through the Zowe desktop.
File API and JES API

The File API server provides a set of REST APIs for working with z/OS data sets and Unix files. These APIs are used by the MVS and USS Explorer apps.

The JES API server provides a set of REST APIs for working with JES. These APIs are used by the JES Explorer application.

Both the File API and JES API servers are registered as tiles on the API catalog, so you can view the Swagger definition and test API requests and responses.

Cross memory server

Unlike all of the servers described above which run under the ZWESVSTC started task as address spaces for USS processes, the cross memory server has its own separate started task ZWESIS01 and its own user ID ZWESIUSR that runs the program ZWESIS01.

Release notes

Learn about what is new, changed, or removed in Zowe™.

Zowe Version 1.11.0 LTS and later releases include the following enhancements, release by release.

- Version 1.11.0 LTS (May 2020)
- Version 1.10.0 LTS (April 2020)
- Version 1.9.0 LTS (February 2020)
- Version 1.8.1 (February 2020)
- Version 1.8.0 (February 2020)
Version 1.11.0 LTS (May 2020)

New features and enhancements

The following features and enhancements were added:

API Mediation Layer

The following new feature was added to the Zowe API Mediation Layer in this version:

• The 'Try it out' functionality has been added to test for public and private endpoints. #258

   API ML Changelog

ZSS

• A new query parameter (?addQualifiers) which can be appended to /datasetMetadata/ allows for searching that
mores closely represents the search behavior of 3.4 #108
• Added support for changing log levels via REST API #173

Zowe App Server

• Updated the JES Explorer, MVS Explorer, and USS Explorer apps to support single sign-on from the Zowe API
Mediation Layer. #344 #345 #346
• Modals in the Editor now have an "X" icon to close the modal. #130
• An event emitter for session changes, login, logout, and sessionExpire for Angular, React, and iFrame applications
has been added #210
• Session events have been added to mvhosting #53
• Updates made to generate_zlux_certificates.sh because apiml_cm.sh has been moved into the zowe-install-
packaging repo #110
• Zowe Web browser plugin, which can be used to view webpages that are not Zowe apps, has been added. #194
• Translations have been added for labels and buttons for password reset forms #215, #218
• Browser-based apiml token, auth simplification #196:

  1. API mediation layer token is now held in the browser upon login via the Desktop. This also allows for the
Desktop to do single-sign-on login with the token if it is already present in the browser.
  2. Auth plugins no longer need to be specified explicitly within the server configuration file, the capability
remains for backwards compatibility. The server will now auto-detect the auth plugins that are available
  3. Auth plugins can now be of more than one type, to satisfy environments that have plugins that need access to
APIs of similar but different types
• New shortcuts have been added to navigate the start menu with a keyboard #213
• Sessions are now maintained based on most recent activity across tabs #219
• Support for password changing, including expired password changing, has been implemented #193

Zowe APIs

Zowe Jobs APIs
- Version 2 APIs now support single sign-on from the Zowe API Mediation Layer #21
- Updated embedded Spring Boot version #89

**Zowe Data Set and Unix Files APIs**

- Version 2 APIs now support single sign-on from the Zowe API Mediation Layer #18
- Updated embedded Spring Boot version #151
- Added incomplete connect timeout parameter to prevent Slowloris DOS attacks #158

**Zowe CLI**

Reference the appropriate version in each of the following changelogs to learn about CLI features, enhancements, and fixes:

**Core CLI Changelogs:**

- Zowe CLI - v6.11.0
- Imperative CLI Framework - v4.6.0
- Secure Credential Store Plug-in - v4.0.4

**CLI Plug-in Changelogs:**

- IBM CICS Plug-in - v4.0.2
- IBM DB2 Plug-in - v4.0.6
- IBM FTP Plug-in - v1.0.2
- IBM IMS Plug-in - v2.0.1
- IBM MQ Plug-in - v2.0.1

**Zowe Explorer**

Review the Zowe Explorer Change Log to learn about the latest features, enhancements, and fixes.

You can install the latest version of the extension from the Visual Studio Code Marketplace.

**Zowe installer**

- Added a `-l` parameter to the Installing Zowe runtime from a convenience build on page 74, Generate certificate with the custom values on page 102, Copy cross memory data set members automatically on page 109, and Step 1: Copy the PROCLIB member ZWESVSTC on page 111 scripts. This parameter allows you to specify where the setup scripts write trace logs.
- Improved port validation to assist determining whether Zowe's ports are available.

**Zowe troubleshooting**

- Improved the troubleshooting script `zowe-support.sh` to assist with offline problem determination. See Capturing diagnostics to assist problem determination on page 289.

**Zowe documentation**

- Added a topic Zowe lifecycle on page 284 that describes the use of the `EXTENDER_COMPONENTS` value in the `instance.env` file. See Extensions on page 107.
- Improved the Zowe architecture on page 13 information to include a more current architecture topology diagram and more details on the individual Zowe services, where they log their data, and how to perform high-level problem determination.
- Added new problem determination scenarios and resolution. See Troubleshooting Zowe Application Framework on page 316
- Added information on how to determine which release of Zowe is installed. See Zowe releases.
- Added a Zowe resources on page 46 topic, which provides a list of resources that supplement the documentation on this site.

**Bug fixes**

The following bugs were fixed:
ZSS

- Bugfix: Fixed a below the line leak in the QSAM code #138

Zowe App Server

- Bugfix: Material dialogs no longer overlap over the login screen #145
- Bugfix: Re-login to same desktop session would duplicate items in the launch menu. In this version, the session is cleared on logout, fixing the duplication issue #208
- Bugfix: Bugfix for websockets to prevent server throwing exception on malformed message #189
- Bugfix: Fixed app server configuration bug where min worker count was ignored when max worker count was not defined #187
- Bugfix: Added missing pluginID argument for setStorageAll method. #191
- Bugfix: app-server agent info was not available to plugins if it was specified via command line arguments #111

Version 1.10.0 LTS (April 2020)

New features and enhancements

The following features and enhancements were added:

API Mediation Layer

The following new feature was added to the Zowe API Mediation Layer in this version:

- Zowe API ML can now use z/OSMF to provide JSON Web Tokens (JWT). #433

ZSS

- Fast EBCDIC to UTF8 character translation is now supported by using the TROO instruction with a "EBCDIC 1047 to ISO/IEC 8859-1" translation table. #127
- Performance improvements in character conversion, JSON and collections code. #162
- The code now prints fewer warnings when attls is not set up. #130
- ZSS logs belonging in the ZSS repo have been refactored so that they now use the Zowe logger and message IDs. #163
- Config variable names have been updated to stay consistent with IBM terminology. #165

Zowe App Server

- The sample-react-app README has been updated to state prerequisites. #20
- An example of how to use the Zowe Desktop's built-in context menu has been added. #31
- Sample angular app has been updated for angular 6 best practices use of HttpClient, RxJS #33
- Simple conda build scripts have been added. #46
- App server logs now have IDs prefixed, for easy lookup in future documentation. #49
- Enhancements for plugin adding. #51
- App server logs now have IDs prefixed, for easy lookup in future documentation #102.
- App server now defaults to prevent apps from being embedded in an iframe that does not come from the same origin. #104
- The jes-explorer has been updated to support Single Sign On functionality offered by the api-layer. #160
- Desktop now has keybindings to minimize (ctrl-alt-down), maximize windows (ctrl-alt-up), and show launchbar menu (ctrl-alt-m). #176
- App server “router”-type dataservices now have a new Storage API within their context object, for standardized in-server state persistence. #178
- App server can now add plugins on-demand without a restart, by re-scanning plugins directory via REST API / plugins. #179
- App server can now be configured to set HTTP headers that will default and possibly override those of the plugins. #180
- App server /auth API now returns which handler is the default. #183
• Events and actions for viewports and windows are now accessible to iframe’s via the standardized window.ZoweZLUX.iframe object. #184
• Focus on app2app, as well as some package updates. #188
• 3 features:
  1. Desktop can now filter the list of apps by search query.
  2. Desktop cleanup has reduced the bootstrapping server requests by half.
  3. Desktop now can load new apps added to the server without a page reload. #189
• Desktop’s DOM now has lang attribute as soon as the language preference is known. #190
• Desktop login screen updated with new Zowe logo. #204
• JES, MVS Explorers now have support for APIML’s Single Sign On feature #344

Zowe CLI

The Secure Credential Store plug-in is now packaged with tools that build dependencies locally. This fixes an issue where the installation could fail at sites with firewall restrictions. #9

Tip: Zowe CLI release notes are now aggregated in changelogs. Reference the appropriate version in each changelog to learn about features, enhancements, and fixes.

Core CLI Changelogs:
• Zowe CLI - v6.10.1
• Secure Credential Store Plug-in - v4.0.3

CLI Plug-in Changelogs:
• IBM CICS Plug-in - v4.0.2
• IBM DB2 Plug-in - v4.0.5
• IBM FTP Plug-in: - v1.0.1
• IBM IMS Plug-in: - v2.0.1
• IBM MQ Plug-in: - v2.0.1

Zowe Explorer

Review the Zowe Explorer Change Log to learn about the latest features, enhancements, and fixes.

You can install the latest version of the extension from the Visual Studio Code Marketplace.

Bug fixes

The following bugs were fixed:

Zowe z/OS Installation

Bugfix: zowe-configure-instance.sh does not allow the -c instance directory location to be an existing Zowe runtime. This caused a deadloop and running out of BPXAS instances. See Unable to create BPXAS instances on page 291. #1123

Zowe App Server
• Bugfix: subloggers would not inherit message translation maps from parent loggers. #24
• Bugfix: sample-angular-app could not be run from a folder outside of $ROOT_DIR. #34
• Bugfix: Menu locations were wrong when multiple apps opened because the numbers used partially came from the previous instance. #36
• Bugfix: Apps that were the target of app2app communication were not put into focus. #50
• Bugfix: Developers could not run app-server without a certificate authority. #98
• Bugfix: App server could not work with self-signed/invalid TLS certificates sometimes used in test/development, because the configuration option broke. The option has been restored. #103
• Bugfix: App server instance settings initialization had inconsistent write permissions. #105
• Bugfix: App server no longer issues warning about failure to load undefined log file. #182
• Bugfix: Fixes unformatted messages when a language is not specified. #186
• Bugfix: Editor would not work for unix files when used through api mediation layer due to encoded slash. #187
• Bugfix: App framework’s right click menu could go off screen vertically at the bottom. #200
• Bugfix: zosmf-auth no longer issues configuration warning during startup. #398
• Doc Bugfix: Sample react app did not state its dependence on the sample angular app. #405
• Bugfix: Substitute zosmf-auth for apiml-auth to remove warning. #1232

Version 1.9.0 LTS (February 2020)
Zowe v1.9.x is designated as the current Zowe Long-term Support (LTS) version.

New features and enhancements
The following features and enhancements were added:

API Mediation Layer
The following new features and enhancements have been made to the Zowe API Mediation Layer in this version:

• Support of special characters has been added to API Mediation Layer core services. In addition, all onboarding enablers now support special characters as well.
• Custom metadata support has been added to the onboarding enablers. Additional parameters can now be easily added to an expandable parameter array. This feature may be used for security configuration in the future.
• Passticket support has been added to API ML Core Services and onboarding enablers. This makes it easier to authenticate existing mainframe applications with the API Mediation Layer.
• New versions of Spring Boot based onboarding enablers (V1 and V2) have been released. These enablers support the new version of the metadata required by the Discovery Service. The new versions of the enablers consume significantly less disk space.

The following bug fixes have been introduced:

• A fix of a critial authentication issue with some versions of z/OSMF has been applied.
• A fix has been applied to support multipart requests.
• A fix has been applied to the z/OSMF authorization header.

Zowe App Server
• Added support for Node.js - z/OS V12. See Installing Node.js on z/OS on page 50 for details.
• A new endpoint for removing dataservices has been added #62
• Functionality for removing data sets has been added #65
• Deletion of data sets and their members is now supported #88
• Deletion of data sets and their members is now supported #85
• The following helper functions have been added to test caller's environment #115:
  • A function to test whether the caller is running in SRB
  • A function to test whether the caller is in cross-memory mode
  • A function to test whether the caller is holding a CPU, CMS, CML or local lock
• The logout endpoint has been re-added for zss #100
• Added support of SRB and locked callers to the Cross-Memory sever's PC space switch routine #153
• This pull request add the following features #120: Ability to use the lock-free queue intrusively which allows a more flexible storage management on the user's side Functions to copy to/from foreign address space using destination/source keys and ALETs
• Reformatted the save as modal in zowe editor #129
• Added snackbar notification for directory error #131
• Removed language server tab in editor #134
• Explicitly call zss for logout to make sure cookies are known to be invalid #28
• The following changes have been made to Zlux server framework logging #174:
  • Added English resource files for messages
  • Added code to all error, warning, debug and informational logged outputs
  • Replaced most console.log calls with logger calls
  • Support for HTTP-Strict-Transport-Security. Custom headers for static content are now available #173
  • Functionality for controlling application access for individual users has been added #216
  • Out-of-band multi-factor authentication is now supported #225

**Zowe CLI**

To leverage the new features and plug-ins available in this version, you must follow the steps in Migrating to Long-term Support (LTS) version on page 118.

The following new CLI plug-ins are added:

- IBM® z/OS FTP Plug-in for Zowe CLI on page 188
- IBM® IMS™ Plug-in for Zowe CLI on page 189
- IBM® MQ Plug-in for Zowe CLI on page 190
- Secure Credential Store Plug-in for Zowe CLI on page 191

The following new features and enhancements are added in this version:

- **Notable Change:** The `zowe zos-files download ds` and `zowe zos-files download uf` commands no longer put the full content in the response format json (`--rfj`) output. More information.
- **Notable Change:** The `--pass` option is changed to `--password` for all commands and profiles (zosmf, cics, etc...). The aliases `--pw` and `--pass` still function. To update a profile, issue the `zowe profiles update` command and use the new option name `--password`.
- **Notable Change:** You can enter `PROMPT*` as a value for any CLI option to enable interactive prompting. If you wrote scripts in which any option is defined with the exact value `PROMPT*`, the script will not execute properly in this version. For more information, see Using the prompt for sensitive options on page 175.
- Zowe CLI was tested and confirmed to run on Unix System Services (USS) on z/OS. For more information, refer to blog Installing Node.js on the Mainframe.
  (The IBM Db2 and Secure Credential Store plug-ins for Zowe CLI will *not* run on z/OS due to native code requirements.)
- The `zowe files copy` command was added for copying the contents of a data set or member to another data set or member. #580
- Zowe CLI now exploits Node.js stream APIs for download and upload of spool files, data sets, and USS files. (#331)
- The following new commands were added for interacting with file systems:
  - `zowe zos-files list fs` #429
  - `zowe zos-files mount fs` #431
  - `zowe zos-files unmount fs` #432
- The following new commands were added for creating USS files and directories:
  - `zowe zos-files create file` #368
  - `zowe zos-files create dir` #368

The IBM® CICS® Plug-in is updated with the following functionality:

- **Notable Change:** The plug-in now uses HTTPS by default when connecting to CMCI. The option `--protocol http` was added to let you override the default as needed. #77
- Define, enable, install, discard, disable, and delete CICS URIMaps. #53 #49 #48 #51 #50 #52
- Define and delete CICS web services. #58 #59
- Add and remove CSD Groups to/from CSD Lists #60.
Zowe Explorer
Review the Zowe Explorer Change Log to learn about the latest features, enhancements, and fixes.
You can install the latest version of the extension from the Visual Studio Code Marketplace.
Watch a video on how to work with data sets using Zowe Explorer.

Bug fixes
The following bugs were fixed:

Zowe App Server
- URL encoding with % sign were always returning with authorization:false with RACF #27
- Users are no longer able to delete the initial “/” in the address bar for selected files #379
- The search bar text for datasets has been changed from “Enter a dataset” to “Enter a dataset query”. The Address bar text for files has been changed from “Enter a directory” to “Enter an absolute path” #60

Version 1.8.1 (February 2020)

Bug fixes for Zowe CLI
A bug was fixed where Zowe CLI installation could fail and users could recieve the following error message when installing Zowe CLI v1.8.0:

```
981 verbose stack Error: EPERM: operation not permitted
```

To install the fix, download the new v1.8.1 package from Zowe.org and retry the installation process.

Version 1.8.0 (February 2020)

New features and enhancements
The following features and enhancements were added.

Installation of Zowe z/OS components
- The installation now just needs two parameters configured: the USS location of the runtime directory and a data set prefix where a SAMPLIB and LOADLIB will be created. The runtime directory permissions are set to 755 and when Zowe is run, no data is written to the runtime directory.
- The way to configure Zowe is changed. Previously, you configured Zowe at installation time with the `zowe-install.yaml` file. This file has been removed and is no longer used in this release.
- A new directory `zowe-instance-dir` has been introduced that contains configuration data used to launch Zowe. This allows more than one Zowe instance to be started from the same Zowe runtime directory. A new file `zowe-instance.env` within each `zowe-instance-dir` directory controls which ports are allocated to the Zowe servers as well as location of any dependencies such as Java, z/OSMF or node. No configuration data is specified at install time. The data is only read, validated and used at launch time. The `zowe-instance.env` file contains a parameter value `LAUNCH_COMPONENT_GROUPS` that allows you to control which Zowe subsystems to launch, for example you can run the Zowe desktop and not the API Mediation Layer, or vice-versa; you can run just the API Mediation Layer and not the Zowe desktop. The `zowe-instance-dir` directory is also where log files are collected. Static extensions to the API Mediation Layer are recorded in the Zowe instance directory as well as any plug-in extensions to the Zowe desktop. This allows the runtime directory to be fully replaced during PTF upgrades or moving to later Zowe releases while preserving configuration data and extension definitions that are held in the instance directory.
- A new directory `keystore-directory` has been introduced outside of the Zowe runtime directory which is where the Zowe certificate is held, as well as the truststore for public certificates from z/OS services that Zowe communicates to (such as z/OSMF). A keystore directory can be shared between multiple Zowe instances and across multiple Zowe runtimes.
- All configuration of z/OS security that was done by Unix shell scripts during installation and configuration has been removed. A JCL member `ZWESECUR` is provided that contains all of the JCL needed to configure
permissions, user IDs and groups, and other steps to prepare and configure a z/OS environment to successfully run Zowe. Code is included for RACF, Top Secret, and ACF/2.

- The Zowe cross memory server installation script `zowe-install-apf-server.sh` is removed. In this release, the steps for configuring z/OS security are included in the ZWESECUR JCL member.
- Previously, Zowe runs its two started tasks under the user ID of IZUSVR and admin of IZUADMIN. These belong to z/OSMF and are no longer used in this release. Instead, Zowe includes two new user IDs of ZWESVUSR (for the main Zowe started task), ZWESIUSR (for the cross memory server), and ZWEEADMIN as a group. These user IDs are defaults and different ones can be used depending on site preferences.
- Previously, the main Zowe started task is called ZOWESVR. Now it is called ZWESVSTC.
- Previously, the cross memory started task is called ZWESIS01. Now it is called ZWESISTC.
- The script `zowe-verify.sh` is no longer included with Zowe. Now the verification is done at launch time and dependent on the launch configuration parameters. It is no longer done with a generic script function that `zowe-verify.sh` used to provide.

For more information about how to install Zowe z/OS components, see Installation roadmap on page 71.

**API Mediation Layer**

- The API Catalog backend has been modified to support the OpenAPI 3.0 version. The API Catalog now supports the display of API documentation in the OpenAPI 3.0 format.
- A new Eureka metadata definition has been developed to enable service registration that does not require using existing pre-prepared enablers. Both new and old metadata versions are supported by the Discovery Service. Corresponding documentation to onboard a service with the Zowe API ML without an onboarding enabler has also been refactored.
- The plain Java enabler has been redesigned for simple and straight-forward API service configuration. Configuration parameters have been refactored to remove duplicates and unused parameters, and improve consistency with other parameters. Documentation to Onboard a REST API service with the Plain Java Enabler (PJE) has also been refactored.

**Zowe App Server**

- The app server now issues a message indicating it is ready, how many plug-ins loaded, and where it can be accessed from #355
- Restructured the App server directories to separate writable configuration items from read-only install content #911 #627 #87 #43
- Move install-app script to instance directory bin folder for ease of use #966
- Access control for app visibility 216
- The following features and enhancements were made in the default apps:
  - UI changes for write support for datasets in editor #340
  - Support for QSAM and VSAM deletion in the ZSS dataset REST API #339
  - Editor: Dataset deletion capability #229
  - Editor: File deletion UI changes #338
  - Editor fix: When saving a new file use the opened directory in the dialog #233
  - Editor fix: Disable text area for datasets in the absence of write ability #342
  - Editor fix: When saving a new file use the opened directory in the dialog #233

**Zowe CLI**

- The Zowe CLI REST API now supports the following capabilities for managing data sets:
  - Rename sequential and partitioned data sets. #571
  - Migrate data sets. #558
  - Copy data sets to another data set and copy members to another member. #578
- The Zowe CLI REST API now supports HTTP ETags in response data. The ETag mechanism allows client applications to cache data more efficiently. ETags can also prevent simultaneous, conflicting updates to a resource. #598
Zowe Explorer
Review the Zowe Explorer Change Log to learn about the latest features, enhancements, and fixes.
You can install the latest version of the extension from the Visual Studio Code Marketplace.
Check the new "Getting Started with Zowe Explorer" video to learn how to install and get started with the extension.
For more information, see Zowe Explorer Extension for VSCode.

Bug fixes
The following bugs were fixed.

Zowe App Server
- Use of environment variables (_TAG_REDIR_XXX) required to run Zowe with node v12 #333
- Install-app.sh sh would not work without first server run, improper permissions #373

Zowe CLI
- Fixed an issue where zowe zos-jobs submit stdin command returned an error when handling data from standard in. #601
- Updated dependencies to address potential vulnerabilities. Most notably, Yargs is upgraded from v8.0.2 to v15.0.2. #333

Version 1.7.1 (December 2019)

New features and enhancements
The following features and enhancements were added.

Zowe App Server
- A backup routine for when a non-administrator tries to access the API. Instead of executing privileged commands and failing, it will execute a command to get their profile, and return only the information in their scope. This is a feature that most people won't need, since you'd ideally want to be an administrator if you were using this API, but the functionality is there. (#114)
- The ability to retrieve profiles only by prefix. This can be done by looking for a profile with a "." at the end. This will act as a wildcard which extracts everything matching that prefix. (#114)

Zowe SMP/E installation
The pre-release of the Zowe SMP/E build is updated to be based on Zowe Version 1.7.1.

Bug fixes
The following bugs were fixed.

Zowe App Server
- Fixed a bug where the end of an acid is cut off when getting the access list of a group, resulting in invalid output in the response. (#114)
- Fixed a bug where all of the different administrator suffixes weren't defined, so it was incorrectly returning administrators. (#114)

Version 1.7.0 (November 2019)

New features and enhancements
The following features and enhancements were added.

API Mediation Layer
- Cleanup Gateway dependency logs (#413)
- Cleanup Gateway - our code (#417)
• Cleanup Discovery Service dependency logs (#403)
• Cleanup Discovery Service - our code (#407)
• External option to activate DEBUG mode for APIML (#410)

**Zowe App Server**

• Introduced the "SJ" feature to the JES Explorer application (#282)

You can now right-click a job label and click "Get JCL" to retrieve the JCL used to submit the job. This JCL can then be edited and resubmitted.

![JES Explorer](image)

• File Explorer now offers a right click Delete option for files and folders (#43)
• Prevented creation/deletion of files and folders queued for deletion. (#48)
• Updated back-end API to give more accurate delete responses. (#93)
• IFrame adapter: added support for plugin definition, logger, and launch metadata. (#174)
• IFrame app-to-app communication support (#174)
• Removed unnecessary warning suppression (#23)
• Dispatcher always sends message, even when context doesn't exist (#174)
• Support constructor injectibles via Iframe adapter (#174)
• Browser tab for the desktop now includes opened app name. (#175)
• File Explorer now offers a right click file and folder Properties menu. (#180)
• File Explorer now offers a right click dataset Properties menu. (#49)
• Made it possible to specify config properties via command line arguments for the App server. (#81)
• Allow override of configuration attributes using a -D argument syntax. (#154)
• Allow specifying environment variables that can be interpreted as JSON structures. (#156)

**Zowe Explorer (Extension for VSCode)**

• The name of the extension was changed from "VSCode Extension for Zowe" to "Zowe Explorer".
• The VSCode Extention for Zowe contains various changes in this this release. For more information, see the VSCode Change Log.

**Bug fixes**

The following bugs were fixed.
**API Mediation Layer**

Fixed a typo in Gateway startup script. (#427)

**Zowe App Server**

Fixed notification click, time stamp, inconsistent notification manager pop up clicks, empty notification bubbles, and safari issue. (#171)

**Zowe CLI**

This version of Zowe CLI contains various bug fixes that address vulnerabilities.

**Version 1.6.0 (October 2019)**

No changes were made to API ML or Zowe CLI in this release.

**What's new in the Zowe App Server**

The following features and enhancements are added:

- Added two NodeJS issues to the App Framework Troubleshooting section. #786
- Added a REST API for new core dataservices to administer the servers and plugins. #82
- Added pass through express router ws patcher in case plug-ins need it. #152, #149
- Updated security plugins to manage proxied headers so that unnecessary things are not put into the browser. #152, #26
- Clear cookie on complete logout. #152

**What's new in Zowe CLI**

The following enhancement was added:

- The --wait-for-output and the --wait-for-active options were added. You can append these options to the `zowe zos-jobs submit` command to either wait for the job to be active, or wait for the job to complete and enter OUTPUT status. If you do not specify --vasc, you can use these options to check job return codes without issuing `zowe zos-jobs view job-status-by-jobid <jobid>`.

**What's new in the Visual Studio Code (VSC) Extension for Zowe**

The Visual Studio Code (VSC) Extension for Zowe lets you interact with data sets and USS files from a convenient graphical interface. Review the Change Log to learn about the latest improvements to the extension.

You can download the latest version from the VSC Marketplace.

**Version 1.5.0 (September 2019)**

**What's new in API Mediation Layer**

The following features and enhancements are added:

- The Discovery Service UI now enables the user to log in using mainframe credentials or by providing a valid client certificate.
- API Catalog REST endpoints now accept basic authentication by requiring the user to provide a username and password.

The following bugs are fixed:

- A defect has been resolved where previously an authentication message was thrown in the service detail page in the API Catalog when the swagger JSON document link was clicked. The message requires the user to provide mainframe credentials but did not link to an option to authenticate. Now, a link is included to provide the user with the option to authenticate.
What's new in the Zowe App Server

The following features and enhancements are added:

- Adds dynamic logging functionality for plugins (#60, #63)
- Top Secret updates to the security lookup API (#71, #72, #74)
- Accept basic auth header as an option for login (#80)
- JSON parsing enhancements for UTF8, and printing to buffer (#67)
- Optimization, memory bugfix and improved tracing for authentication (#72)
- Performance optimization for app thumbnail snapshots: Fixed a bug causing slowdown relative to number of apps open (#131)
- Translations: Added missing language translations about session lifecycle (#137)
- Logger reorganized for Zowe-wide log format unification. Includes i18n-able message ID support & new info. See #90 (#17, #119, #116, #142, #35, #19, #132, #146, #126, #139, #67, #133, #21)
- Establish rules & recommendations for conformance (#142)
- Launchbar menu of apps now has same context menu properties as pinned apps (#140)
- Properties App now shows the ID of the chosen plugin (#140)
- Added group permission for plugin access when installing via install script (#125)
- Updated URIBroker include new parameter for searching datasets with included trailing qualifiers (#34, #138)
- App2App communication now allows you to target a specific app instance, as well as to request minimization or maximization (#38, #148)
- Configuration Dataservice now can load plugin defaults from the plugin's own folder (#129)
- Configuration Dataservice can now support GET like HEAD (#140)
- Configuration Dataservice can now utilize binaries as opposed to JSON. This mode does not process the objects, just stores & retrieves. (#130)
- Added a notification menu, popup & API where messages can be sent by administrators to individual or all end users (#36, #144)
- Doc: Configuration Dataservice Swagger document updated for new features (#136)
- Desktop now supports loading a custom wallpaper, and the launchbar & maximized window style has been changed to improve screen real estate (#151)
- The App Server configuration and log verbosity can now be viewed and updated on-the-fly via a REST API (#66, #128)
- The App Server environment parameters and log output can now be viewed via a REST API (#66, #128)
- The App Server can now have Application plugins added, removed, and upgraded on-the-fly via a REST API (#137, #69)
- A dataservice can now import another import dataservice, as long as this chain eventually resolves to a non-import dataservice (#139)
- You can now open any Zowe App in its own browser tab by right clicking its icon and choosing "Open in new browser window" (#149, #150)
- Icons improved for datasets that are migrated/archived (#30)
- Support App2App to open a given dataset (#87, #35)
- Navigate the editor menu bar via keyboard (#85)
- Add keyboard shortcuts to open and close tabs (#81)
- Add loading indicator for dataset loading (#34)
- Compress the terminals with gzip for improved initial load time, same as was done with the editor previously (#22, #23)
- Made the following enhancements to the JES Explorer App
  - Add ability to open and view multiple Spool files at once (#99)
  - Migrate from V0 to V1 of Material UI (#98)
  - Migrate from V15 to V16 of React (#98)

The following bugs are fixed:
• New directories/files from Unix file API would have no permissions (#75)
• Properties App can now be reused when clicking property of a second app (#140)
• Logout did not clear dispatcher App instance tracking (#32)
• Iframe Apps were not gaining mouse focus correctly (#37, #145)
• Remove placeholder swagger from swagger response when plugin-provided swagger is found (#139)
• ZSS Dataservices could fail due to incorrect impersonation environment variable setting (_BPX_SHAREAS) (#68)
• Restore focus of text on window restore (#84)
• Reposition menu from menu bar on edge/firefox (#82)
• Could not open the SSH terminal in single window mode (#21)

What’s new in Zowe CLI and Plug-ins

The following commands and enhancements are added:

• You can append --help-web to launch interactive command help in your Web browser. For more information, see Interactive Web Help. (#238)

Zowe SMP/E Alpha (August 2019)

A pre-release of the Zowe SMP/E build is now available. This alpha release is based on Zowe Version 1.4.0. Do not use this alpha release in production environment.

• To obtain the SMP/E build, go to the Zowe Download website.
• For more information, see Installing Zowe SMP/E on page 77.

Version 1.4.0 (August 2019)

What’s new in API Mediation Layer

This release of Zowe API ML contains the following improvements:

• JWT token configuration
  • RS256 is used as a token encryption algorithm
  • JWT secret string is generated at the time of installation and exported as a .pem file for use by other services
  • JWT secret string is stored in a key store in PKCS 11 format under "jwtsecret" name
• SonarQube problems fixed
• Various fixes from SonarQube scan
• API Mediation Layer log format aligned with other Zowe services:
  
  %d{yyyy-MM-dd HH:mm:ss,UTC} %clr($logbackService:- $logbackServiceName):%thread:${PID:- }&gt;{(magenta) %X{userid:-} %clr(%-5level) %clr(\%logger{15},%file:%line\)}(cyan) %msg%n

• Added an NPM command to register certificates on Windows. The following command installs the certificate to trusted root certification authorities:

  npm run register-certificates-win

• Cookie persistence changed
  • Changed the API Mediation Layer cookie from persistent to session. The cookie gets cleared between browser sessions.
• Fixed high CPU usage occurrence replicated in Broadcom (#282)
• Changed configuration of LatencyUtils to decrease idle CPU consumption by API ML services
• API Mediation layer now builds using OpenJDK with OpenJ9 JVM
What's new in the Zowe App Server

Made the following fixes and enhancements:

- Added the ability for the App Server Framework to defer to managers for dataservices that are not written in NodeJS or C. The first implementation is a manager of Java servlet type dataservices, where the App Server manages Tomcat instances when Tomcat is present. (#158)
- Added a tomcat xml configuration file with substitutions for values (ports, keys, certificates) necessary for the App Server to manage one or more instances of Tomcat for hosting servlet dataservices. Also added a new section to the zluxserver.json file to describe dataservice providers such as the aforementioned Tomcat Java Servlet one. (#49)
- Added Swagger API documentation support. Application developers can include a Swagger 2.0 JSON or YAML file in the app's /doc/swagger directory for each REST data service. Each file must have the same name as the data service. Developers can then reference the files at runtime using a new app route: /ZLUX/plugins/PLUGINID/catalogs/swagger. They can reference individual services at: /ZLUX/plugins/PLUGINID/catalogs/swagger/SERVICENAME. If swagger documents are not present, the server will use contextual knowledge to show some default values. (#159)
- The following new REST and cross-memory services have been added (#32):
  - Extract RACF user profiles
  - Define/delete/permit general RACF resource profiles (limited to a single class)
  - Add/remove RACF groups
  - Connect users to RACF groups (for a limited set of group prefixes)
  - Check RACF user access levels (limited to a single class)
- Fixed multiple issues in the File Editor App. (#88)
- Fixed multiple ZSS file and dataset API issues (#49 #42 #40 #44 #45)
- Remove several CSS styles from the Desktop to prevent bleed-in of styles to Apps (#117)
- Fixed incorrect count of open Apps upon logging in more than once per browser session (#123) Add OMVS information API to uribroker (#116)
- Enhanced auth plugin structure for application framework that lists auth capabilities (#118 #14 #19)
- Improved searching for node libraries for dataservices within an plugin (#114)
- Editor & File Explorer Widget Changes
  - Unix directory listing now starts in the user's home directory (#16)
  - JCL syntax coloring revision (#73)
  - Cursor, scroll position and text selection is now kept while switching tabs in editor (#71)
  - Editor now scrolls tab bar to newest tab when opening, and tab scrolling improved when closing tabs (#69)
  - Tab name, tooltip, and scroll fixes (#55 #60 #63)
  - Change in double and single click behavior of file explorer widget (#21)
  - Fix to show language menu on new file (#62)
  - Fix to keep language menu within the bounds of app window (#59)
  - Fix to the delete file prompt (#61)
  - Fix to allow closing of multiple editor instances (#22)
  - Fix to query datasets correctly by making queries uppercase (#65)
- Fixed issue where the cascading position of new windows were wrong when that application was maximized. (#102)
- Fixed issue where the file tabs in File Editor app were vertically scrollable, and where the close button would not be accessible for long file names. (#170)
- Updated the package lock files in all repositories to fix vulnerable dependencies. (#163)
- Fixed an issue where the Desktop used the roboto-latin-regular font for all text, which would not display well with non-latin languages. Now the fallback font is sans-serif. (#118)

What's new in Zowe CLI and Plug-ins

You can now explore the Zowe CLI command help in an interactive online format. See Zowe CLI Web Help.
The following new commands and enhancements are added:

- The **VSCode Extension for Zowe** now supports manipulation of USS files. (#32)
- You can now archive z/OS workflows using a wildcard. (#435)
- The z/OS Workflows functionality is now exported to an API. Developers can leverage the exported APIs to create applications and scripts without going through the CLI layer. (#482)
- The CLI now exploits all "z/OS data set and file REST interface" options that are provided in z/OSMF v2.3. (#491)

The following bugs are fixed:

- Fixed an issue where examples for zowe files list uss-files were slightly incorrect. (#440)
- Improved error message for zowe db2 call procedure command. (#22)

**Version 1.3.0 (June 2019)**

**What’s new in API Mediation Layer**

This release of Zowe API ML contains the following user experience improvements:

- Added authentication endpoints (/login, /query) to the API Gateway
- Added the Gateway API Swagger document (#305)
  - Fixed the bug that causes JSON response to set incorrectly when unauthenticated
  - Fixed error messages shown when a home page cannot be modified
- Added a new e2e test for GW, and update the detail service tile (#309)
- Removed a dependency of integration-enabler-java on the gateway-common (#302)
- Removed access to the Discovery service UI with basic authentication (#313)
- Fixed the issue with the connection logic on headers to pass in the websocket (#275)
- Fixed the bug 264: Bypass the API Gateway when the server returns 302 (#276)
- Fixed the issue that causes the API ML Services display as UP, and makes the API doc available in the Catalog regardless whether the API ML Services stop (#287)
- Fixed the issue that prevents the API Catalog to load under zLux 9 (314)

**What’s new in the Zowe App Server**

Made the following fixes and enhancements:

- Added internationalization to the Angular and React sample applications. (#133)
- Made the following enhancements to the ZSS server:
  - Added support for Zowe on z/OS version 2.4. (#15)
  - Updated documentation for query parameter to file API (#48)
- Made the following enhancements to security:
  - App Server session cookie is now a browser session cookie rather than having an expiration date. Expiration is now tracked on the server side. (#132, #97, #81)
  - Added a "mode=base64" option to the unixfile API. (#127)
- Added a port to the cookie name to differentiate multiple servers on same domain. (#95)
- Made the following fixes and enhancements to the Code Editor application:
  - Added a menu framework to provide options specific to the current file/data set type. (#131)
  - Added ISPF-like syntax highlighting for JCL. (#48)
  - Fixed an issue by notifying users if the editor cannot open a file or data set. (#148)
  - Fixed an issue with event behavior when a tab is closed. (#135)
  - Fixed an issue with not showing the content of files in Chrome and Safari. (#100)
  - Fixed an issue with files shown without alphabetical sorting. (#85)
• Made the following fixes and enhancements to the TN3270 application (#96):
  • Fixed an issue where the application could not be configured to default to a TLS connection.
  • Fixed an issue where it could not handle a TN3270 connection, only TN3270E. Improved preference saving.
    Administrators can now store default values for terminal mod type, codepage, and screen dimensions.
• Made the following fixes and enhancements for App2App for IFrames (#24, #107):
  • Fixed an issue with an exception when handling App2App communication with IFrames.
  • Added experimental support for App2App communication with an IFrame application as destination.
• Made the following enhancements to support TopSecret:
  • Added a user-profiles endpoint. (#113)
  • Added an endpoint extraction for groups. (#129)
  • Fixed an issue with app names not being internationalized when translations were present. (#85)
  • Fixed Russian language errors in translation files. (#100)
  • Fixed several issues with using the Application Server as a proxy. (#93)
  • Fixed an issue with the App Server throwing exceptions when authorization plugins were installed but not requested. (#94)
  • Fixed an issue with ZSS consuming excessive CPU during download. (#147)
  • Fixed documentation issue by replacing "zLUX" with "Zowe Application Framework" and "MVD" with "Zowe Desktop." (#214)
  • Fixed an issue with an incorrect translation for word "Japanese" in Japanese. (#108)

\textbf{What's new in Zowe CLI and Plug-ins}

The following new commands and enhancements are added:
• Return a list of archived z/OSMF workflows with the \texttt{zowe zos-workflows list arw} command. (#391)
• Return a list of systems that are defined to a z/OSMF instance with the \texttt{zowe zosmf list systems} command. (#348)
• The \texttt{zowe uss issue ssh} command now returns the exit code of the shell command that you issued. (#359)
• The \texttt{zowe files upload dtu} command now supports the metadata file named \texttt{.zosattributes}. (#366)

The following bugs are fixed:
• Fixed an issue where \texttt{zowe workflow ls aw} commands with the \texttt{--wn} option failed if there was a space in
  the workflow name. (#356)
• Fixed an issue where \texttt{zowe zowe-files delete uss} command could fail when resource URL includes a
  leading forward-slash. (#343).

\textbf{Version 1.2.0 (May 2019)}

Version 1.2.0 contains the following changes since Version 1.1.0.

\textbf{What's new in the Zowe installer}

• Made the following installer improvements:
  • Check whether ICSF is configured before checking Node version to avoid runaway CPU.
  • Warn if the host name that is determined by the installer is not a valid IP address.
  • Fixed a bug where a numeric value is specified in ZOWE_HOST_NAME causing errors generating the Zowe certificate.
• Made the following improvements to the \texttt{zowe-check-prereqs.sh} script:
  • Improvements for checking and validating the telnet and ssh port required by the Zowe Desktop applications.

\textbf{What's new in API Mediation Layer}

This release of Zowe API ML contains the following user experience improvements:
• Prevented the Swagger UI container on the service detail page from spilling.
• Added a check for the availability of the z/OSMF URL contained in the configuration. z/OSMF is used to verify users logging into the Catalog.
• Made PageNotFound error visible only in the debug log level.
• Added zD&T-compatible ciphers and the TLS protocol restricted to 1.2.
• Introduced support for VSCode development.
• Introduced a common cipher configuration property.
• Fixed URL transformation defects.
• Fixed reporting that the Catalog is down when it is started before the Discovery Service.
• Removed the bean overriding error message from the log.
• Fixed the state manipulation mechanism in the Catalog. As a result, no restoring of the application state is performed.
• Fixed the Catalog routing mechanism for a users who is already logged in so that the user is not prompted to log in again.
• A timeout has been set for Catalog login when z/OSMF is not responding.
• A tile change in the Catalog is now propagated to the UI.
• Fixed a problem with an incorrect service homepage link in the Catalog.
• The Catalog Login button has been disabled when the login request is in progress.

What's new in the Zowe App Server

• Improved security by adding support for RBAC (Role Based Access Control) to enable Zowe to determine whether a user is authorized to access a dataservice.
• Added Zowe Desktop settings feature for specifying the Zowe desktop language.
• Added German language files.
• Fixed a bug by adding missing language files.
• Enabled faster load times by adding support for serving the Zowe Application Framework core components, such as the Desktop, as compressed files in gzip format.
• Added support for application plug-ins to serve static content, such as HTML, JavaScript, and images, to browsers in gzip and brotli compressed files.
• Fixed a Code Editor bug by separating browsing of files and data sets.

What's new in Zowe CLI and Plug-ins

The Zowe CLI core component contains the following improvements and fixes:

• The zos-uss command group is added to the core CLI. The commands let you issue Unix System Services shell commands by establishing an SSH connection to an SSH server. For more information, see zos-uss on page 178.
• The zowe zos-workflows command group now contains the following active-workflow-details options:
  • --steps-summary-only | --sso (boolean): An optional parameter that lets you list (only) the steps summary.
  • --skip-workflow-summary | --sws (boolean): An optional parameter that lets you skip the default workflow summary.
• Zowe CLI was updated to correct an issue where the zowe zos-workflows start command ignored the -- workflow-name argument.
• Updated and clarified the description the -- overwrite option for the zowe zos-workflows create workflow-from-data-set command and the Zowe zos-workflows create workflow-from-uss-file command.
• The CLI Reference Guide is featured on the Zowe Docs home page. The document is a comprehensive guide to commands and options in Zowe CLI.
• You can now click the links on the Welcome to Zowe help section and open the URL in a browser window. Note that the shell application must support the capability to display and click hyperlinks.
What's new in Zowe USS API

Made the following enhancements:

• Chtag detection and ascii/ebcdic conversion on GET & PUT requests. For details, see this issue.
• New optional header on GET Unix file content request to force conversion from ebcdic to ascii. For details, see this issue.
• New response header on GET Unix file content requests: E-Tag for overwrite detection and validation. For details, see this issue.
• Reintroduced PUT (update) Unix file content endpoint. For details, see this issue.
• Reintroduced DELETE Unix file content endpoint. For details, see this issue.
• Reintroduced POST (create) Unix file or directory endpoint. For details, see this issue.
• Fixed a problem with incorrect return error when the user requests to view contents of a USS folder they do not have permission to. Now it returns a 403 (Forbidden) error. For details, see this issue.

Version 1.1.0 (April 2019)

Version 1.1.0 contains the following changes since the last 1.0.x version.

What’s new in Zowe system requirements

z/OSMF Lite is now available for non-production use such as development, proof-of-concept, demo and so on. It simplifies the setup of z/OSMF with only a minimal amount of z/OS customization, but provides key functions that are required. For more information, see Configuring z/OSMF Lite (for non-production use) on page 54.

What’s new in the Zowe App Server

• Made the following user experience improvements:
  • Enabled the Desktop to react to session expiration information from the Zowe Application Server. If a user is active the Desktop renews their session before it expires. If a user appears inactive they are prompted and can click to renew the session. If they don't click, they are logged out with a session expired message.
  • Added the ability to programmatically dismiss popups created with the "zlux-widgets" popup manager.
• Made the following security improvements:
  • Encoded URIs shown in the App Server 404 handler, which prevents some browsers from loading malicious scripts.
  • Documented and support configuring HTTPS on ZSS.
  • For ZSS API callers, added HTTP response headers to instruct clients not to cache HTTPS responses from potentially sensitive APIs.
  • Improved the Zowe Editor App by adding app2app communication support that allows the application to open requested directories, dataset listings, and files.
  • Improved the Zowe App API by allowing subscription to close events on viewports instead of windows, which allows applications to better support Single App Mode.
  • Fixed a bug that generated an extraneous RACF audit message when you started ZSS.
  • Fixed a bug that would sometimes move application windows when you attempted to resized them.
  • Fixed a bug in the "Getting started with the ZOWE WebUi" tutorial documentation.
  • Fixed a bug that caused applications that made ZSS service requests to fail with an HTTP 401 error because of dropped session cookies.

What's new in the Zowe CLI and Plug-ins

This release of Zowe CLI contains the following new and improved capabilities:

• Added APIs to allow the definition of workflows
• Added the option max-concurrent-requests to the zowe zos-files upload dir-to-uss command
• Added the option overwrite to the zowe zos-workflows create commands
- Added the option workflow-name to the zowe zos-workflows commands
- Added the following commands along with their APIs:
  - zowe zos-workflows archive active-workflow
  - zowe zos-workflows create workflow-from-data-set
  - zowe zos-workflows create workflow-from-uss-file
  - zowe zos-workflows delete active-workflow
  - zowe zos-files list uss-files

This release of the Plug-in for IBM DB2 Database contains the following new and improved capabilities:

- Implemented command line precedence, which lets users issue commands without the need of a DB2 profile.
- The DB2 plug-in can now be influenced by the ZOWE_OPT_ environment variables.

What's new in API Mediation Layer

- Made the following user experience improvements:
  - Documented the procedure for changing the log level of individual code components in Troubleshooting API ML.
  - Documented a known issue when the API ML stops accepting connections after z/OS TCP/IP is recycled in the Troubleshooting API ML.

Version 1.0.1 (March 2019)

Version 1.0.1 contains the following changes since the last version.

What's new in Zowe installation on z/OS

During product operation of the Zowe Cross Memory Server which was introduced in V1.0.0, the z/OSMF user ID IZUSVR or its equivalent must have UPDATE access to the BPX.SERVER and BPX.DAEMON FACILITY classes. The install script will do this automatically if the installing user has enough authority, or provide the commands to be issued manually if not. For more information, see Installing the Zowe Cross Memory Server on z/OS.

What's new in the Zowe App Server

- Made the following improvements to security:
  - Removed the insecure SHA1 cipher from the Zowe App Server's supported ciphers list.
  - Added instructions to REST APIs to not cache potentially sensitive response contents.
  - Set secure attributes to desktop and z/OSMF session cookies.
  - Fixed a bug that caused the configuration data service to mishandle PUT operations with bodies that were not JSON.
  - Fixed a bug that prevented IFrame applications from being selected by clicking on their contents.
  - Fixed various bugs in the File Explorer and updated it to use newer API changes.
  - Fixed a bug in which App2App Communication Actions could be duplicated upon logging in a second time on the same desktop.

What's new in Zowe CLI

- Create and Manage z/OSMF Workflows using the new zos-workflows command group. For more information, see Zowe CLI command groups on page 176
- Use the @lts-incremental tag when you install and update Zowe CLI core or plug-ins. The tag ensures that you don't consume breaking changes that affect your existing scripts. Installation procedures are updated to reflect this change.
- A Zowe CLI quick start on page 40 is now available for users who are familiar with command-line tools and want to get up and running quickly.
- IBM CICS Plug-in for Zowe CLI was updated to support communication over HTTPS. Users can enable https by specifying --protocol https when creating a profile or issuing a command. For backwards compatibility, HTTP remains the default protocol.
Getting Started

What's new in the Zowe REST APIs

Introduced new Unix files APIs that reside in the renamed API catalog tile z/OS Datasets and Unix files service (previously named z/OS Datasets service). You can use these APIs to:

- List the children of a Unix directory
- Get the contents of a Unix file

What's changed

- **Zowe explorer apps**
  - JES Explorer: Enhanced Info/Error messages to better help users diagnose problems.
  - MVS Explorer: Fixed an issue where Info/Error messages were not displayed when loading a Dataset/Members contents.

Version 1.0.0 (February 2019)

Version 1.0.0 contains the following changes since the Open Beta release.

What's new in API Mediation Layer

- HTTPs is now supported on all Java enablers for onboarding API microservices with the API ML.
- SSO authentication using z/OSMF has been implemented for the API Catalog login. Mainframe credentials are required for access.

What's new in Zowe CLI

- **Breaking change to Zowe CLI**: The `--pass` command option is changed to `--password` for all core Zowe CLI commands for clarity and to be consistent with plug-ins. If you have zosmf profiles that you created prior to January 11, 2019, you must recreate them to use the `--password` option. The aliases `--pw` and `--pass` still function when you issue commands as they did prior to this breaking change. You do not need to modify scripts that use `--pass`.
- The `@next` npm tag used to install Zowe CLI is deprecated. Use the `@latest` npm tag to install the product with the online registry method.

What's new in the Zowe Desktop

- You can now obtain information about an application by right-clicking on an application icon and then clicking Properties.
- To view version information for the desktop, click the avatar in the lower right corner of the desktop.
- Additional information was added for the Workflow application.
- The titlebar of the active window is now colored to give an at-a-glance indication of which window is in the foreground.
- Window titlebar maximize button now changes style to indicate whether a window is maximized.
- Windows now have a slight border around them to help see boundaries and determine which window is active.
- Multiple instances of the same application can be opened and tracked from the launchbar. To open multiple instances, right-click and choose Open New. Once multiple instances are open, you can click the application icon to select which application to bring to the foreground. The number of orbs below the application icon relates to the number of instances of the application that is open.
- Desktop framework logging trimmed and formalized to the Zowe App Logger. For more information, see https://github.com/zowe/zlux/wiki/Logging.
- The UriBroker was updated to support dataservice versioning and UNIX file API updates.
- Removed error messages about missing components.js by making this optional component explicitly declared within an application. By using the property "webContent.hasComponents = true/false".
- Set the maximum username and password length for login to 100 characters each.
- Applications can now list webContent.framework = “angular” as an alias for “angular2”.
- Fixed a bug where the desktop might not load on high latency networks.
What's new in the Zowe App Server

- HTTP support was disabled in favor of HTTPS-only hosting.
- The server can be configured to bind to specific IPs or to hostnames. Previously, the server would listen on all interfaces. For more information, see https://github.com/zowe/zlux-app-server/pull/30.
- The core logger prefixes for the Zowe App Server were changed from "_unp" to "_zsf".
- Dataservices are now versioned, and dataservices can depend on specific versions of other dataservices. A plug-in can include more than one version of a dataservice for compatibility. For more information, see https://github.com/zowe/zlux/wiki/ZLUX-Dataservices.
- Support to communicate with the API Mediation Layer with the use of keys and certificates was added.
- Trimmed and corrected error messages regarding unconfigured proxies for clarity and understanding. For more information, see https://github.com/zowe/zlux-server-framework/pull/33.
- Fixed the nodeCluster.sh script to have its logging and environment variable behavior consistent with nodeServer.sh.
- Removed the "swaggerui" plug-in in favor of the API Catalog.
- Bugfix for /plugins API to not show the installation location of the plug-in.
- Bugfix to print a warning if the server finds two plug-ins with the same name.
- Added the ability to conditionally add HTTP headers for secure services to instruct the browser not to cache the responses. For more information, see https://github.com/zowe/zlux-server-framework/issues/36.
- Added a startup check to confirm that ZSS is running as a prerequisite of the Zowe App Server.
- Bugfix for sending HTTP 404 response when content is missing, instead of a request hanging.
- Added tracing of login, logout, and HTTP routing so that administrators can track access.

What's changed

- Previously, APIs for z/OS Jobs services and z/OS Data Set services are provided unsing an IBM WebSphere Liberty web application server. In this release, they are provided using a Tomcat web application server. You can view the associated API documentation corresponding to the z/OS services through the API Catalog.
- References to zlux-example-server were changed to zlux-app-server and references to zlux-proxy-server were changed to zlux-server-framework.

Known issues

Paste operations from the Zowe Desktop TN3270 and VT Terminal applications

TN3270 App - If you are using Firefox, the option to use Ctrl+V to paste is not available. Instead, press Shift + right-click to access the paste option through the context menu.

Pressing Ctrl+V will perform paste for the TN3270 App on other browsers.

VT Terminal App - In the VT Terminal App, Ctrl+V will not perform a paste operation for any browser.

Note: In both terminals, press Shift + right-click to access copy and paste options through the context menu.

z/OS Subsystems App - The z/OS Subsystems application is being removed temporarily for the 1.0 release. The reason is that as the ZSS has transitioned from closed to open source some APIs needed to be re-worked and are not complete yet. Look for the return of the application in a future update.

Zowe CLI quick start

Get started with Zowe™ CLI quickly and easily.

Note: This section assumes some prerequisite knowledge of command-line tools and writing scripts. If you prefer more detailed instructions, see Installing Zowe CLI on page 116

- Installing on page 41
  - Installing Zowe CLI core
  - Installing CLI plug-ins on page 41
Getting Started

- Issuing your first commands on page 41
- Listing all data sets under a high-level qualifier (HLQ) on page 41
- Downloading a partitioned data-set (PDS) member to local file on page 42
- Using profiles on page 42
  - Profile types on page 42
  - Creating a zosmf profile on page 42
  - Using a zosmf profile on page 42
- Writing scripts on page 42
  - Example: on page 42
- Next Steps on page 43

Installing

Software Requirements
Before you install Zowe CLI, download and install Node.js and npm. Use an LTS version of Node.js that is compatible with your version of npm. For a list of compatible versions, see Node.js Previous Releases.

(Windows only): On graphical Linux, install gnome-keyring and libsecret on your computer before you install the Secure Credential Store. On headless Linux, follow the procedure documented in the SCS plug-in Readme.

Installing Zowe CLI core from public npm
Issue the following commands in sequence to install the core CLI.
The "core" includes Zowe CLI and Secure Credential Store, which enhances security by encrypting your username and password.

```
npm install @zowe/cli@zowe-v1-lts -g
```
```
zowe plugins install @zowe/secure-credential-store-for-zowe-cli@zowe-v1-lts
```

Installing CLI plug-ins
```
zowe plugins install @zowe/cics-for-zowe-cli@zowe-v1-lts @zowe/db2-for-zowe-cli@zowe-v1-lts @zowe/ims-for-zowe-cli@zowe-v1-lts @zowe/mq-for-zowe-cli@zowe-v1-lts @zowe/zos-ftp-for-zowe-cli@zowe-v1-lts
```

The command installs most open-source plug-ins, but the IBM Db2 plug-in requires Installing on page 186.
For more information, see Installing Zowe CLI plug-ins on page 181.

Issuing your first commands
Issue `zowe --help` to display full command help. Append `--help` (alias `-h`) to any command to see available command actions and options.

To interact with the mainframe, type `zowe` followed by a command group, action, and object. Use options to specify your connection details such as password and system name.

Listing all data sets under a high-level qualifier (HLQ)
```
zowe zos-files list data-set "MY.DATASET.*" --host my.company.com --port 123 --user myusername123 --pass mypassword123
```
Downloading a partitioned data-set (PDS) member to local file

```bash
zowe zos-files download data-set "MY.DATA.SET(member)" -f "mylocalfile.txt" --host my.company.com --port 123 --user myusername123 --pass mypassword123
```

See Zowe CLI command groups on page 176 for a list of available functionality.

Using profiles

Zowe profiles let you store configuration details such as username, password, host, and port for a mainframe system. Switch between profiles to quickly target different subsystems and avoid typing connection details on every command.

Profile types

Most command groups require a zosmf-profile, but some plug-ins add their own profile types. For example, the CICS plug-in has a cics-profile. The profile type that a command requires is defined in the PROFILE OPTIONS section of the help response.

Tip: The first zosmf profile that you create becomes your default profile. If you don't specify any options on a command, the default profile is used. Issue zowe profiles -h to learn about listing profiles and setting defaults.

Creating a zosmf profile

```bash
zowe profiles create zosmf-profile myprofile123 --host my.company.com --port 123 --user myusername123 --password mypassword123
```

Note: The port defaults to 443 if you omit the --port option. Specify a different port if your host system does not use port 443.

Using a zosmf profile

```bash
zowe zos-files download data-set "MY.DATA.SET(member)" -f "mylocalfile.txt" --zosmf-profile myprofile123
```

For detailed information about issuing commands, using profiles, and storing variables as environment variables, see Defining Zowe CLI connection details on page 136

Writing scripts

You can write Zowe CLI scripts to streamline your daily development processes or conduct mainframe actions from an off-platform automation tool such as Jenkins or TravisCI.

Example:

You want to delete a list of temporary datasets. Use Zowe CLI to download the list, loop through the list, and delete each data set using the zowe zos-files delete command.

```bash
#!/bin/bash
set -e

# Obtain the list of temporary project data sets
dslist=$(zowe zos-files list dataset "my.project.ds*")

# Delete each data set in the list
IFS='\n'
for ds in $dslist
do
  echo "Deleting Temporary Project Dataset: $ds"
  zowe files delete ds "$ds" -f
```
For more information, see Writing scripts to automate mainframe actions on page 179

**Next Steps**

You successfully installed Zowe CLI, issued your first commands, and wrote a simple script! Next, you might want to:

- Review Zowe CLI command groups on page 176 to learn what functionality is available, and explore the in-product help.
- Learn about Defining Environment Variables on page 138 to store configuration options.
- Integrate your scripts with an automation server like Jenkins.
- See what Extending Zowe CLI on page 180 for the CLI.
- Learn about Developing a new plug-in on page 205 (contributing to core and developing plug-ins).

**Frequently Asked Questions**

Check out the following FAQs to learn more about the purpose and function of Zowe™.

- Zowe FAQ on page 43
- Zowe CLI FAQ on page 45

**Zowe FAQ**

**What is Zowe?**

Zowe is an open source project within the Open Mainframe Project that is part of The Linux Foundation. The Zowe project provides modern software interfaces on IBM z/OS to address the needs of a variety of modern users. These interfaces include a new web graphical user interface, a script-able command-line interface, extensions to existing REST APIs, and new REST APIs on z/OS.

**Who is the target audience for using Zowe?**

Zowe technology can be used by a variety of mainframe IT and non-IT professionals. The target audience is primarily application developers and system programmers, but the Zowe Application Framework is the basis for developing web browser interactions with z/OS that can be used by anyone.

**What language is Zowe written in?**

Zowe consists of several components. The primary languages are Java and JavaScript. Zowe CLI is written in TypeScript.

**What is the licensing for Zowe?**

Zowe source code is licensed under EPL2.0. For license text click here and for additional information click here.

In the simplest terms (taken from the FAQs above) - "...if you have modified EPL-2.0 licensed source code and you distribute that code or binaries built from that code outside your company, you must make the source code available under the EPL-2.0."

**Why is Zowe licensed using EPL2.0?**

The Open Mainframe Project wants to encourage adoption and innovation, and also let the community share new source code across the Zowe ecosystem. The open source code can be used by anyone, provided that they adhere to the licensing terms.
What are some examples of how Zowe technology might be used by z/OS products and applications?

The Zowe Desktop (web user interface) can be used in many ways, such as to provide custom graphical dashboards that monitor data for z/OS products and applications.

Zowe CLI can also be used in many ways, such as for simple job submission, data set manipulation, or for writing complex scripts for use in mainframe-based DevOps pipelines.

The increased capabilities of RESTful APIs on z/OS allows APIs to be used in programmable ways to interact with z/OS services.

What is the best way to get started with Zowe?

Zowe provides a convenience build that includes the components released-to-date, as well as IP being considered for contribution, in an easy to install package on Zowe.org. The convenience build can be easily installed and the Zowe capabilities seen in action.

To install the complete Zowe solution, see Introduction on page 48.

To get up and running with the Zowe CLI component quickly, see Zowe CLI quick start on page 40.

What are the prerequisites for Zowe?

The primary prerequisites is Java on z/OS and the z/OS Management Facility enabled and configured. For a complete list of software requirements listed by component, see System requirements on page 48.

How is access security managed on z/OS?

Zowe components use typical z/OS System authorization facility (SAF) calls for security.

How is access to the Zowe open source managed?

The source code for Zowe is maintained on an Open Mainframe Project GitHub server. Everyone has read access. "Committers" on the project have authority to alter the source code to make fixes or enhancements. A list of Committers is documented in Committers to the Zowe project.

How do I get involved in the open source development?

The best way to get started is to join a Zowe Slack channel and/or email distribution list and begin learning about the current capabilities, then contribute to future development.

For more information about emailing lists, community calendar, meeting minutes, and more, see the Zowe Community GitHub repo.

For information and tutorials about extending Zowe with a new plug-in or application, see Onboarding Overview on page 211 on Zowe Docs.

When will Zowe be completed?

Zowe will continue to evolve in the coming years based on new ideas and new contributions from a growing community.

Can I try Zowe without a z/OS instance?

IBM has contributed a free hands-on tutorial for Zowe. Visit the Zowe Tutorial page to learn about adding new applications to the Zowe Desktop and and how to enable communication with other Zowe components.

The Zowe community is also currently working to provide a vendor-neutral site for an open z/OS build and sandbox environment.

Zowe is also compatible with IBM z/OSMF Lite for non-production use. For more information, see Configuring z/OSMF Lite (for non-production use) on page 54 on Zowe Docs.
Zowe CLI FAQ

Why might I use Zowe CLI versus a traditional ISPF interface to perform mainframe tasks?

For developers new to the mainframe, command-line interfaces might be more familiar than an ISPF interface. Zowe CLI lets developers be productive from day-one by using familiar tools. Zowe CLI also lets developers write scripts that automate a sequence of mainframe actions. The scripts can then be executed from off-platform automation tools such as Jenkins automation server, or manually during development.

With what tools is Zowe CLI compatible?

Zowe CLI is very flexible; developers can integrate with modern tools that work best for them. It can work in conjunction with popular build and testing tools such as Gulp, Gradle, Mocha, and Junit. Zowe CLI runs on a variety of operating systems, including Windows, macOS, and Linux. Zowe CLI scripts can be abstracted into automation tools such as Jenkins and TravisCI.

Where can I use the CLI?

<table>
<thead>
<tr>
<th>Usage Scenario</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interactive use, in a command prompt</td>
<td>Perform one-off tasks such as submitting a batch job.</td>
</tr>
<tr>
<td>or bash terminal</td>
<td></td>
</tr>
<tr>
<td>Interactive use, in an IDE terminal</td>
<td>Download a data set, make local changes in your editor,</td>
</tr>
<tr>
<td></td>
<td>then upload the changed dataset back to the mainframe.</td>
</tr>
<tr>
<td>Scripting, to simplify repetitive</td>
<td>Write a shell script that submits a job, waits for the job to</td>
</tr>
<tr>
<td>tasks</td>
<td>complete, then returns the output.</td>
</tr>
<tr>
<td>Scripting, for use in automated</td>
<td>Add a script to your Jenkins (or other automation tool) pipeline to</td>
</tr>
<tr>
<td>pipelines</td>
<td>move artifacts from a mainframe development system to a test system.</td>
</tr>
</tbody>
</table>

Which method should I use to install Zowe CLI?

You can install Zowe CLI using the following methods:

- **Local package installation**: The local package method lets you install Zowe CLI from a zipped file that contains the core application and all plug-ins. When you use the local package method, you can install Zowe CLI in an offline environment. We recommend that you download the package and distribute it internally if your site does not have internet access.

- **Online NPM registry**: The online NPM (Node Package Manager) registry method unpacks all of the files that are necessary to install Zowe CLI using the command line. When you use the online registry method, you need an internet connection to install Zowe CLI

How can I get help with using Zowe CLI?

- You can get help for any command, action, or option in Zowe CLI by issuing the command ‘zowe --help’.
- For information about the available commands in Zowe CLI, see Zowe CLI command groups on page 176.
- If you have questions, the Zowe Slack space is the place to ask our community!

How can I use Zowe CLI to automate mainframe actions?

- You can automate a sequence of Zowe CLI commands by writing bash scripts. You can then run your scripts in an automation server such as Jenkins. For example, you might write a script that moves your Cobol code to a mainframe test system before another script runs the automated tests.
- Zowe CLI lets you manipulate data sets, submit jobs, provision test environments, and interact with mainframe systems and source control management, all of which can help you develop robust continuous integration/delivery.

How can I contribute to Zowe CLI?

As a developer, you can extend Zowe CLI in the following ways:
• Build a plug-in for Zowe CLI
• Contribute code to the core Zowe CLI
• Fix bugs in Zowe CLI or plug-in code, submit enhancement requests via GitHub issues, and raise your ideas with the community in Slack.

**Note:** For more information, see *How can I contribute?* on page 197.

**Zowe resources**

User Guide

Topics:

- Planning and preparing the installation
- Installing Zowe z/OS components
- Installing Zowe CLI
- Advanced Zowe configuration
- Using Zowe
- Zowe CLI extensions and plugins
Planning and preparing the installation

Introduction

The installation of Zowe™ consists of two independent processes: installing the Zowe runtime on z/OS and installing Zowe CLI on a desktop computer.

The Zowe z/OS runtime provides a web desktop that runs in a web browser providing a number of applications for z/OS users, together with an API mediation layer that provides capabilities useful for z/OS developers.

Zowe CLI can connect to z/OS servers and allows tasks to be performed through a command line interface.

- A desktop computer that accesses the Zowe z/OS runtime through a web browser or REST API client does not need to have Zowe CLI installed.
- The z/OS servers that Zowe CLI connects to does not require the Zowe z/OS components to be installed on those servers.
- A desktop computer that uses Zowe CLI does not require the Zowe z/OS runtime to be installed on the z/OS server.

Before you start the installation, review the information on system requirements and other considerations.

Planning the installation of Zowe z/OS components

The following information is required during the installation process of the Zowe z/OS components.

- The zFS directory where you will install the Zowe runtime files and folders.
- A HLQ that the installation can create a load library and samplib containing load modules and JCL samples required to run Zowe.
- Multiple instances of Zowe can be started from the same Zowe z/OS runtime. Each launch of Zowe has its own zFS directory that is known as an instance directory.
- Zowe uses a zFS directory to contain its northbound certificate keys as well as a truststore for its southbound keys. Northbound keys are one presented to clients of the Zowe desktop or Zowe API Gateway, and southbound keys are for servers that the Zowe API gateway connects to. The certificate directory is not part of the Zowe runtime so that it can be shared between multiple Zowe runtimes and have its permissions secured independently.
- Zowe has two started tasks.
  - ZWESVSTC brings up the Zowe runtime containing the Zowe desktop, the API mediation layer and a number of Zowe applications.
  - ZWESISSTC is a cross memory server that the Zowe desktop uses to perform APF-authorized code. More details on the cross memory server are described in Installing and configuring the Zowe cross memory server (ZWESISSTC) on page 108.

In order for the two started tasks to run correctly, security manager configuration needs to be performed. This is documented in Configuring the z/OS system for Zowe on page 96 and a sample JCL member ZWESECUR is shipped with Zowe that contains commands for RACF, TopSecret, and ACF2 security managers.

System requirements

Before installing Zowe™, ensure that your environment meets the prerequisites.

- Common system requirements
- Zowe Application Framework requirements
- Zowe CLI requirements
- Multi-Factor Authentication for Zowe Desktop on page 49

Common z/OS system requirements (host)

- z/OS Version 2.2 or later.
• IBM z/OS Management Facility (z/OSMF) Version 2.2, Version 2.3 or Version 2.4.

z/OSMF is an optional prerequisite for Zowe. It is recommended that z/OSMF is present to fully exploit Zowe's capabilities.

::: tip
• For non-production use of Zowe (such as development, proof-of-concept, demo), you can customize the configuration of z/OSMF to create what is known as "z/OS MF Lite" that simplifies the setup of z/OSMF. As z/OS MF Lite only supports selected REST services (JES, DataSet/File, TSO and Workflow), you will observe considerable improvements in start up time as well as a reduction in the efforts involved in setting up z/OSMF. For information about how to set up z/OSMF Lite, see Configuring z/OSMF Lite (for non-production use) on page 54
• For production use of Zowe, see Configuring z/OSMF on page 51. :::

Zowe Application Framework requirements (host)

• Node.js
  • On z/OS: Node.js v6.x starting with v6.14.4, v8.x (except v8.16.1), and v12.x. Note when using v12.x, it is highly recommended that plugins used are tagged. For more information, see Tagging on z/OS

To install Node.js on z/OS, follow the instructions in Installing Node.js on z/OS on page 50.
• IBM SDK for Java Technology Edition V8 or later
• 833 MB of zFS file space
• (client) Supported browsers:
  • Google Chrome V66 or later
  • Mozilla Firefox V60 or later
  • Safari V12.0 or later
  • Microsoft Edge 17 (Windows 10)

Each release of the Zowe Application Framework is tested to work on the current releases of Chrome, Firefox, Safari, and Edge, as well as the oldest release within a 1 year time span, unless the current release is also older than 1 year. For Firefox, the oldest supported release will also be from the Extended Support Release (ESR) version of Firefox, to ensure compatibility in those enterprise environments. This scheme for browser support is to ensure that Zowe works on the vast majority of browsers that people are currently using, while still allowing for use of new features and security that browsers constantly add.

If you do not see your product listed here, please contact the Zowe community so that it can be validated and included.

Multi-Factor Authentication for Zowe Desktop

To enable multi-factor authentication, you must install IBM Z Multi-Factor Authentication. For information on using MFA in Zowe, see Multi-factor authentication configuration on page 132.

Zowe CLI requirements (client)

Zowe CLI is supported on platforms where Node.js 8.0 or 10 is available, including Windows, Linux, and Mac operating systems. Zowe CLI was also tested and confirmed to run on Unix System Services (USS) on z/OS.

• Install Node.js V8.0 or higher LTS versions
  Tip: You might need to restart the command prompt after installing Node.js. Issue the command node --version to verify that Node.js is installed.
• Install a version of Node Package Manager (npm) that is compatible with your version of Node.js. For a list of compatible versions, see Node.js Previous Releases.
  Tip: npm is included with the Node.js installation. Issue the command npm --version to verify the version of npm that is installed.
• **(Optional)** If you plan to install plug-ins, review the Software requirements for Zowe CLI plug-ins on page 180.

**Free disk space**

Zowe CLI requires approximately **100 MB** of free disk space. The actual quantity of free disk space consumed might vary depending on the operating system where you install Zowe CLI.

**Installing Node.js on z/OS**

Before you install Zowe™, you must install IBM SDK for Node.js on the same z/OS server that hosts the Zowe Application Server. Review the information in this topic to obtain and install Node.js.

- Supported Node.js versions on page 50
- How to obtain IBM SDK for Node.js - z/OS on page 50
- Hardware and software prerequisites on page 50
- Installing the PAX edition of Node.js - z/OS on page 51
- Installing the SMP/E edition of Node.js - z/OS on page 51

**Supported Node.js versions**

The following Node.js versions are supported to run Zowe. See the Hardware and software prerequisites on page 50 section for the prerequisites that are required by Zowe.

The corresponding IBM Knowledge Center for Node.js - z/OS lists all the prerequisites for Node.js. Some software packages, which might be listed as prerequisites there, are **NOT** required by Zowe. Specifically, you do **NOT** need to install Python, Make, Perl, or C/C++ runtime or compiler. If you can run `node --version` successfully, you have installed the prerequisites required by Zowe.

- **v6.x starting with v6.14.4**
  - z/OS V2R2 with PTF UI46658 or z/OS V2R3
- **v8.x (except v8.16.1)**
  - z/OS V2R2: PTFs UI62788, UI46658, UI62416 (APARs PH10606, PI79959, PH10740)
  - z/OS V2R3: PTFs UI61308, UI61376, and UI61747 (APARs PH07107, PH08353, and PH09543)

**Known issue:** There is a known issue with node.js v8.16.1 and Zowe desktop encoding. See the GitHub issue for details.

- **v12.x**

**How to obtain IBM SDK for Node.js - z/OS**

You can obtain IBM SDK for Node.js - z/OS for free in one of the following ways:

- Order the SMP/E edition through your IBM representative for production use
- Use the PAX evaluation edition for non-production deployments

For more information, see the blog "How to obtain IBM SDK for Node.js - z/OS, at no charge".

**Hardware and software prerequisites**

To install Node.js for Zowe, the following requirements must be met.

The corresponding IBM Knowledge Center for Node.js - z/OS lists all the prerequisites for Node.js. Some software packages, which might be listed as prerequisites there, are **NOT** required by Zowe. Specifically, you do **NOT** need to install Python, Make, Perl, or C/C++ runtime or compiler.

If you can run `node --version` successfully, you have installed the Node.js prerequisites required by Zowe.

**Hardware:**
IBM zEnterprise® 196 (z196) or newer

Software:

• z/OS UNIX System Services enabled
• Integrated Cryptographic Service Facility (ICSF) configured and started

ICSF is required for Node.js to operate successfully on z/OS. If you have not configured your z/OS environment for ICSF, see z/OS Cryptographic Services ICSF Administrators Guide. To see whether ICSF has been started, check whether the started task ICSF or CSF is active.

Installing the PAX edition of Node.js - z/OS

Follow these steps to install the PAX edition of Node.js - z/OS to run Zowe.
1. Download the pax.Z file to a z/OS machine.
2. Extract the pax.Z file inside an installation directory of your choice. For example:
   
   ```bash
   pax -rf <path_to_pax.Z_file> -x pax
   ```
3. Add the full path of your installation directory to your PATH environment variable:
   
   ```bash
   export PATH=<installation_directory>/bin/:$PATH
   ```
4. Run the following command from the command line to verify the installation.
   
   ```bash
   node --version
   ```
   
   If Node.js is installed correctly, the version of Node.js is displayed.
5. After you install Node.js, set the NODE_HOME environment variable to the directory where Node.js is installed. For example, NODE_HOME=/proj/mvd/node/installs/node-v6.14.4-os390-s390x.

Installing the SMP/E edition of Node.js - z/OS

To install the SMP/E edition of Node.js, see the documentation for IBM SDK for Node.js - z/OS. Remember that the software packages Perl, Python, Make, or C/C++ runtime or compiler that the Node.js documentation might mention are NOT needed by Zowe.

Configuring z/OSMF

The following information contains procedures and tips for meeting z/OSMF requirements. For complete information, go to IBM Knowledge Center and read the following documents.

• IBM z/OS Management Facility Configuration Guide
• IBM z/OS Management Facility Help

z/OS requirements

Ensure that the z/OS system meets the following requirements:

<table>
<thead>
<tr>
<th>Requirements</th>
<th>Description</th>
<th>Resources in IBM Knowledge Center</th>
</tr>
</thead>
<tbody>
<tr>
<td>AXR (System REXX)</td>
<td>z/OS uses AXR (System REXX) component to perform Incident Log tasks. The component enables REXX executable files to run outside of conventional TSO and batch environments.</td>
<td>System REXX</td>
</tr>
<tr>
<td>Requirements</td>
<td>Description</td>
<td>Resources in IBM Knowledge Center</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Common Event Adapter (CEA) server</td>
<td>The CEA server, which is a co-requisite of the Common Information Model (CIM) server, enables the ability for z/OSMF to deliver z/OS events to C-language clients.</td>
<td>Customizing for CEA</td>
</tr>
<tr>
<td>Common Information Model (CIM) server</td>
<td>z/OSMF uses the CIM server to perform capacity-provisioning and workload-management tasks. Start the CIM server before you start z/OSMF (the IZU* started tasks).</td>
<td>Reviewing your CIM server setup</td>
</tr>
<tr>
<td>CONSOLE and CONSPROF commands</td>
<td>The CONSOLE and CONSPROF commands must exist in the authorized command table.</td>
<td>Customizing the CONSOLE and CONSPROF commands</td>
</tr>
<tr>
<td>Java level</td>
<td>IBM® 64-bit SDK for z/OS®, Java Technology Edition V8 or later is required.</td>
<td>Software prerequisites for z/OSMF</td>
</tr>
<tr>
<td>TSO region size</td>
<td>To prevent <em>exceeds maximum region size</em> errors, verify that the TSO maximum region size is a minimum of 65536 KB for the z/OS system.</td>
<td>N/A</td>
</tr>
<tr>
<td>User IDs</td>
<td>User IDs require a TSO segment (access) and an OMVS segment. During workflow processing and REST API requests, z/OSMF might start one or more TSO address spaces under the following job names: userid; substr(userid, 1, 6) CN (Console).</td>
<td>N/A</td>
</tr>
</tbody>
</table>

**Configuring z/OSMF**

**Follow these steps:**

1. From the console, issue the following command to verify the version of z/OS:

   ```
   /D IPLINFO
   ```

   Part of the output contains the release, for example,

   ```
   RELEASE z/OS 02.02.00.
   ```
2. Configure z/OSMF.

z/OSMF is a base element of z/OS V2.2 and V2.3, so it is already installed. But it might not be configured and running on every z/OS V2.2 and V2.3 system.

In short, to configure an instance of z/OSMF, run the IBM-supplied jobs IZUSEC and IZUMKFS, and then start the z/OSMF server. The z/OSMF configuration process occurs in three stages, and in the following order:

- Stage 1 - Security setup
- Stage 2 - Configuration
- Stage 3 - Server initialization

This stage sequence is critical to a successful configuration. For complete information about how to configure z/OSMF, see Configuring z/OSMF if you use z/OS V2.2 or Setting up z/OSMF for the first time if V2.3.

**Note:** In z/OS V2.3, the base element z/OSMF is started by default at system initial program load (IPL). Therefore, z/OSMF is available for use as soon as you set up the system. If you prefer not to start z/OSMF automatically, disable the autostart function by checking for START commands for the z/OSMF started procedures in the COMMNDxx parmlib member.

The z/OS Operator Consoles task is new in Version 2.3. Applications that depend on access to the operator console such as Zowe™ CLI's RestConsoles API require Version 2.3.

1. Verify that the z/OSMF server and angel processes are running. From the command line, issue the following command:

   ```
   /D A,IZU*
   ```

   If jobs IZUANG1 and IZUSVR1 are not active, issue the following command to start the angel process:

   ```
   /S IZUANG1
   ```

   After you see the message "CWWKB0056I INITIALIZATION COMPLETE FOR ANGEL", issue the following command to start the server:

   ```
   /S IZUSVR1
   ```

   The server might take a few minutes to initialize. The z/OSMF server is available when the message "CWWKF0011I: The server zosmfServer is ready to run a smarter planet." is displayed.

2. Issue the following command to find the startup messages in the SDSF log of the z/OSMF server:

   ```
   f IZUG349I
   ```

   You could see a message similar to the following message, which indicates the port number:

   **IZUG349I:** The z/OSMF STANDALONE Server home page can be accessed at https://mvs.hursley.ibm.com:443/zosmf after the z/OSMF server is started on your system.

   In this example, the port number is 443. You will need this port number later.

   Point your browser at the nominated z/OSMF STANDALONE Server home page and you should see its Welcome Page where you can log in.

**Note:** If your implementation uses an external security manager other than RACF (for example, CA Top Secret for z/OS or CA ACF2 for z/OS), you provide equivalent commands for your environment. For more information, see the following product documentation:

- Configure z/OS Management Facility for CA Top Secret
- Configure z/OS Management Facility for CA ACF2
z/OSMF REST services for the Zowe CLI

The Zowe CLI uses z/OSMF Representational State Transfer (REST) APIs to work with system resources and extract system data. Ensure that the following REST services are configured and available.

<table>
<thead>
<tr>
<th>z/OSMF REST services</th>
<th>Requirements</th>
<th>Resources in IBM knowledge Center</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud provisioning services</td>
<td>Cloud provisioning services are required for the Zowe CLI CICS and Db2 command groups. Endpoints begin with /zosmf/provisioning/</td>
<td>Cloud provisioning services</td>
</tr>
<tr>
<td>TSO/E address space services</td>
<td>TSO/E address space services are required to issue TSO commands in the Zowe CLI. Endpoints begin with /zosmf/tsoApp</td>
<td>TSO/E address space services</td>
</tr>
<tr>
<td>z/OS console services</td>
<td>z/OS console services are required to issue console commands in the Zowe CLI. Endpoints begin with /zosmf/restconsoles/</td>
<td>z/OS console</td>
</tr>
<tr>
<td>z/OS data set and file REST interface</td>
<td>z/OS data set and file REST interface is required to work with mainframe data sets and UNIX System Services files in the Zowe CLI. Endpoints begin with /zosmf/restfiles/</td>
<td>z/OS data set and file interface</td>
</tr>
<tr>
<td>z/OS jobs REST interface</td>
<td>z/OS jobs REST interface is required to use the zos-jobs command group in the Zowe CLI. Endpoints begin with /zosmf/restjobs/</td>
<td>z/OS jobs interface</td>
</tr>
<tr>
<td>z/OSMF workflow services</td>
<td>z/OSMF workflow services is required to create and manage z/OSMF workflows on a z/OS system. Endpoints begin with /zosmf/workflow/</td>
<td>z/OSMF workflow services</td>
</tr>
</tbody>
</table>

Zowe uses symbolic links to the z/OSMF bootstrap.properties, jvm.security.override.properties, and ltpa.keys files. Zowe reuses SAF, SSL, and LTPA configurations; therefore, they must be valid and complete.

For more information, see Using the z/OSMF REST services in IBM z/OSMF documentation.

To verify that z/OSMF REST services are configured correctly in your environment, enter the REST endpoint into your browser. For example: https://mvs.ibm.com:443/zosmf/restjobs/jobs

Notes:

- Browsing z/OSMF endpoints requests your user ID and password for defaultRealm; these are your TSO user credentials.
- The browser returns the status code 200 and a list of all jobs on the z/OS system. The list is in raw JSON format.

Configuring z/OSMF Lite (for non-production use)

This section provides information about requirements for z/OSMF Lite configuration.
Disclaimer: z/OSMF Lite can be used in a non-production environment such as development, proof-of-concept, demo and so on. It is not for use in a production environment. To use z/OSMF in a production environment, see Configuring z/OSMF on page 51.

   • Appendix B. Modifying IZUSVR1 settings on page 70
   • Appendix C. Adding more users to z/OSMF

Introduction
IBM® z/OS® Management Facility (z/OSMF) provides extensive system management functions in a task-oriented, web browser-based user interface with integrated user assistance, so that you can more easily manage the day-to-day operations and administration of your mainframe z/OS systems.

By following the steps in this guide, you can quickly enable z/OSMF on your z/OS system. This simplified approach to set-up, known as "z/OSMF Lite", requires only a minimal amount of z/OS customization, but provides the key functions that are required by many exploiters, such as the open mainframe project (Zowe™).

A z/OSMF Lite configuration is applicable to any future expansions you make to z/OSMF, such as adding more optional services and plug-ins.

It takes 2-3 hours to set up z/OSMF Lite. Some steps might require the assistance of your security administrator.

For detailed information about various aspects of z/OSMF configuration such as enabling the optional plug-ins and services, see the IBM publication z/OSMF Configuration Guide.

Assumptions
This document is intended for a first time z/OSMF setup. If z/OSMF is already configured on your system, you do not need to create a z/OSMF Lite configuration.

This document is designed for use with a single z/OS system, not a z/OS sysplex. If you plan to run z/OSMF in a sysplex, see z/OSMF Configuration Guide for multi-system considerations.
It is assumed that a basic level of security for z/OSMF is sufficient on the z/OS system. IBM provides a program, IZUNUSEC, to help you set up basic security for a z/OSMF Lite configuration.

System defaults are used for the z/OSMF environmental settings. Wherever possible, it is recommended that you use the default values. If necessary, however, you can override the defaults by supplying an IZUPRMxx member, as described in Appendix A. Creating an IZUPRMxx parmlib member on page 69.

It is recommended that you use the following procedures as provided by IBM:

- Started procedures IZUSVR1 and IZUANG1
- Logon procedure IZUFPROC

Information about installing these procedures is provided in Copying the IBM procedures into JES PROCLIB on page 61.

**Software Requirements**

Setting up z/OSMF Lite requires that you have access to a z/OS V2R2 system or later. Also, your z/OS system must meet the following minimum software requirements:

- **Minimum Java level** on page 56
- **WebSphere® Liberty profile (z/OSMF V2R3 and later)**
- **System settings** on page 57
- **Web browser** on page 57

**Minimum Java level**

Java™ must be installed and operational on your z/OS system, at the required minimum level. See the table that follows for the minimum level and default location. If you installed Java in another location, you must specify the JAVA_HOME statement in your IZUPRMxx parmlib member, as described in Appendix A. Creating an IZUPRMxx parmlib member on page 69.

<table>
<thead>
<tr>
<th>z/OS Version</th>
<th>Minimum level of Java™</th>
<th>Recommended level of Java</th>
<th>Default location</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OS V2R2</td>
<td>IBM® 64-bit SDK for z/OS®, Java Technology Edition V7.1 (SR3), with the PTFs for APAR PI71018 and APAR PI71019 applied <strong>OR</strong> IBM® 64-bit SDK for z/OS®, Java Technology Edition V8, with the PTF for APAR PI72601 applied.</td>
<td>IBM® 64-bit SDK for z/OS®, Java™ Technology Edition, V8 SR6 (5655-DGH)</td>
<td>/usr/lpp/java/J7.1_64</td>
</tr>
<tr>
<td>z/OS V2R3</td>
<td>IBM® 64-bit SDK for z/OS®, Java™ Technology Edition, V8 SR4 FP10 (5655-DGH)</td>
<td>IBM® 64-bit SDK for z/OS®, Java™ Technology Edition, V8 SR6 (5655-DGH)</td>
<td>/usr/lpp/java/J8.0_64</td>
</tr>
</tbody>
</table>

**WebSphere® Liberty profile (z/OSMF V2R3 and later)**

z/OSMF V2R3 uses the Liberty Profile that is supplied with z/OS, rather than its own copy of Liberty. The WebSphere Liberty profile must be mounted on your z/OS system. The default mount point is: /usr/lpp/liberty_zos. To determine whether WebSphere® Liberty profile is mounted, check for the existence of the mount point directory on your z/OS system.

If WebSphere® Liberty profile is mounted at a non-default location, you need to specify the location in the IZUSVR1 started procedure on the keyword **WLPDIR**. For details, see Appendix B. Modifying IZUSVR1 settings on page 70.
Note: Whenever you apply PTFs for z/OSMF, you might be prompted to install outstanding WebSphere Liberty service. It is recommended that you do so to maintain z/OSMF functionality.

System settings

Ensure that the z/OS host system meets the following requirements:

- Port 443 (default port) is available for use.
- The system host name is unique and maps to the system on which z/OSMF Lite will be configured.

Otherwise, you might encounter errors later in the process. If you encounter errors, see Troubleshooting problems on page 68 for the corrective actions to take.

Web browser

For the best results with z/OSMF, use one of the following web browsers on your workstation:

- Microsoft Internet Explorer Version 11 or later
- Microsoft Edge (Windows 10)
- Mozilla Firefox ESR Version 52 or later.

To check your web browser’s level, click About in the web browser.

Creating a z/OSMF nucleus on your system

The following system changes are described in this chapter:

- Running job IZUNUSEC to create security on page 57
- Running job IZUMKFS to create the z/OSMF user file system
- Copying the IBM procedures into JES PROCLIB on page 61
- Starting the z/OSMF server
- Accessing the z/OSMF Welcome page
- Mounting the z/OSMF user file system at IPL time

The following sample jobs that you might use are included in the package and available for download:

- IZUAUTH
- IZUICSEC
- IZUNUSEC_V2R2
- IZUNUSEC_V2R3
- IZUPRM00
- IZURFSEC
- IZUTSSEC
- IZUWFSEC

Download sample jobs

Check out the video for a demo of the process:

Running job IZUNUSEC to create security

The security job IZUNUSEC contains a minimal set of RACF® commands for creating security profiles for the z/OSMF nucleus. The profiles are used to protect the resources that are used by the z/OSMF server, and to grant users access to the z/OSMF core functions. IZUNUSEC is a simplified version of the sample job IZUSEC, which is intended for a more complete installation of z/OSMF.

Note: If your implementation uses an external security manager other than RACF (for example, CA Top Secret or CA ACF2), provide equivalent commands for your environment. For more information, see the following CA Technologies product documentation:

- Configure z/OS Management Facility for CA Top Secret
- Configure z/OS Management Facility for CA ACF2
**Before you begin**

In most cases, you can run the IZUNUSEC security job without modification. To verify that the job is okay to run as is, ask your security administrator to review the job and modify it as necessary for your security environment. If security is not a concern for the host system, you can run the job without modification.

**Procedure**

1. If you run z/OS V2R2 or V2R3, download job IZUNUSEC in the sample jobs package and upload this job to z/OS. If you run z/OS V2R4, locate job IZUNUSEC at SYS1.SAMPLIB.

2. Review and edit the job, if necessary.

3. Submit IZUNUSEC as a batch job on your z/OS system.

4. Connect your user ID to IZUADMIN group.
   a. Download job IZUAUTH in the sample jobs package and customize it.
   b. Replace the 'userid' with your z/OSMF user ID.
   c. Submit the job on your z/OS system.

**Results**

Ensure the IZUNUSEC job completes with return code 0000.

To verify, check the results of the job execution in the job log. For example, you can use SDSF to examine the job log:

1. In the SDSF primary option menu, select Option ST.
2. On the SDSF Status Display, enter S next to the job that you submitted.
3. Check the return code of the job. The job succeeds if '0000' is returned.

**Common errors**

Review the following messages and the corresponding resolutions as needed:

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Message IKJ56702I: INVALID data is issued</td>
<td>The job is submitted more than once.</td>
<td>You can ignore this message.</td>
</tr>
<tr>
<td>Job fails with an authorization error.</td>
<td>Your user ID lacks superuser authority.</td>
<td>Contact your security admin to run IZUNUSEC. If you are using RACF®, select a user ID with SPECIAL attribute which can issue all RACF® commands.</td>
</tr>

</table>

**Running job IZUMKFS to create the z/OSMF user file system**

The job IZUMKFS initializes the z/OSMF user file system, which contains configuration settings and persistence information for z/OSMF.

The job mounts the file system. On a z/OS V2R3 system with the PTF for APAR PI92211 installed, the job uses mount point /global/zosmf. Otherwise, for an earlier system, the job mounts the file system at mount point /var/zosmf.
**Before you begin**

To perform this step, you need a user ID with "superuser" authority on the z/OS host system. For more information about how to define a user with superuser authority, see the publication *z/OS UNIX System Services*.

**Procedure**

1. In the system library SYS1.SAMPLIB, locate job IZUMKFS.
2. Copy the job.
3. Review and edit the job:
   - Modify the job information so that the job can run on your system.
   - You must specify a volume serial (VOLSER) to be used for allocating a data set for the z/OSMF data directory.
4. Submit IZUMKFS as a batch job on your z/OS system.

**Results**

The z/OSMF file system is allocated, formatted, and mounted, and the necessary directories are created.

To verify if the file system is allocated, formatted, locate the following messages in IZUMKFS job output.

```
IDC0002I IDCAMS PROCESSING COMPLETE. MAX CONDITION CODE WAS 0.
IOEZ00077I HFS-compatibility aggregate izu.sizuusrd has been successfully created.
```

Sample output:
Review the following messages and the corresponding resolutions as needed

<td>Job fails with FSM error.</td>
<td>Your user ID lacks superuser authority.</td>
<td>For more information about how to define a user with superuser authority, see the publication <em>z/OS UNIX System Services</em>.</td>
</tr>
</tbody>
</table>
Symptom | Cause | Resolution
--- | --- | ---
Job fails with an authorization error | Job statement errors | See Troubleshooting problems on page 68.

**Copying the IBM procedures into JES PROCLIB**

Copy the z/OSMF started procedures and logon procedure from SYS1.PROCLIB into your JES concatenation. Use `$D PROCLIB` command to display your JES2 PROCLIB definitions.

**Before you begin**

Locate the IBM procedures. IBM supplies procedures for z/OSMF in your z/OS order:

- ServerPac and CustomPac orders: IBM supplies the z/OSMF procedures in the SMP/E managed proclib data set. In ServerPac and SystemPac, the default name for the data set is SYS1.IBM.PROCLIB.
- CBPDO orders: For a CBPDO order, the SMP/E-managed proclib data set is named as SYS1.PROCLIB.
- Application Development CD.

**Procedure**

Use ISPF option 3.3 or 3.4 to copy the procedures from SYS1.PROCLIB into your JES concatenation.

- IZUSVR1
- IZUANG1
- IZUFPROC

**Results**

The procedures now reside in your JES PROCLIB.

**Common errors**

Review the following messages and the corresponding resolutions as needed

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not authorized to copy into PROCLIB</td>
<td>Your user ID doesn't have the permission to modify PROCLIB</td>
<td>Contact your security administrator.</td>
</tr>
<tr>
<td>Abend code B37 or E37</td>
<td>The data set runs out of space</td>
<td>Use IEBCOPY utility to compress PROCLIB dataset before you copy it</td>
</tr>
</tbody>
</table>

**Starting the z/OSMF server**

z/OSMF processing is managed through the z/OSMF server, which runs as the started tasks IZUANG1 and IZUSVR1. z/OSMF is started with the START command.

**Before you begin**

Ensure that you have access to the operations console and can enter the START command.

**Procedure**

In the operations console, enter the START commands sequentially:

```
S IZUANG1
S IZUSVR1
```

Note: The z/OSMF angel (IZUANG1) must be started before the z/OSMF server (IZUSVR1).

You must enter these commands manually at subsequent IPLs. If necessary, you can stop z/OSMF processing by entering the STOP command for each of the started tasks IZUANG1 and IZUSVR1.
Note: z/OSMF offers an autostart function, which you can configure to have the z/OSMF server started automatically. For more information about the autostart capability, see z/OSMF Configuration Guide.

Results

When the z/OSMF server is initialized, you can see the following messages displayed in the operations console:

CWWKB0069I: INITIALIZATION IS COMPLETE FOR THE IZUANG1 ANGEL PROCESS.
IZUG400I: The z/OSMF Web application services are initialized.
CWWKF0011I: The server zosmfServer is ready to run a smarter planet.

Accessing the z/OSMF Welcome page

At the end of the z/OSMF configuration process, you can verify the results of your work by opening a web browser to the Welcome page.

Before you begin

To find the URL of the Welcome page, look for message IZUG349I in the z/OSMF server job log.

Procedure

1. Open a web browser to the z/OSMF Welcome page. The URL for the Welcome page has the following format:

   https://hostname:port/zosmf/

   Where:

   - `hostname` is the host name or IP address of the system in which z/OSMF is installed.
   - `port` is the secure port for the z/OSMF configuration. If you specified a secure port for SSL encrypted traffic during the configuration process through parmlib statement HTTP_SSL_PORT, port is required to log in. Otherwise, it is assumed that you use the default port 443.

2. In the z/OS USER ID field on the Welcome page, enter the z/OS user ID that you use to configure z/OSMF.
3. In the z/OS PASSWORD field, enter the password or pass phrase that is associated with the z/OS user ID.
4. Select the style of UI for z/OSMF. To use the desktop interface, select this option. Otherwise, leave this option unselected to use the tree view UI.
5. Click Log In.
Results

If the user ID and password or pass phrase are valid, you are authenticated to z/OSMF. The Welcome page of IBM z/OS Management Facility tab opens in the main area. At the top right of the screen, Welcome <your_user_ID> is displayed. In the UI, only the options you are allowed to use are displayed.

You have successfully configured the z/OSMF nucleus.

Common errors

The following errors might occur during this step:

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>z/OSMF welcome page does not load in your web browser.</td>
<td>The SSL handshake was not successful. This problem can be related to the browser certificate.</td>
<td>See Certificate error in the Mozilla Firefox browser.</td>
</tr>
<tr>
<td>To log into z/OSMF, enter a valid z/OS user ID and password. Your account might be locked after too many incorrect log-in attempts.</td>
<td>The user ID is not connected to the IZUADMIN group.</td>
<td>Connect your user ID to the IZUADMIN group.</td>
</tr>
<tr>
<td>To log into z/OSMF, enter a valid z/OS user ID and password. Your account might be locked after too many incorrect log-in attempts.</td>
<td>The password is expired.</td>
<td>Log on to TSO using your z/OS User ID and password, you will be asked to change your password if it’s expired.</td>
</tr>
</tbody>
</table>

Mounting the z/OSMF user file system at IPL time

Previously, in Running job IZUMKFS to create the z/OSMF user file system, you ran job IZUMKFS to create and mount the z/OSMF user file system. Now you should ensure that the z/OSMF user file system is mounted automatically for subsequent IPLs. To do so, update the BPXPRMxx parmlib member on your z/OS system.
Before you begin

By default, the z/OSMF file system uses the name IZU.SIZUUSRD, and is mounted in read/write mode. It is recommended that this file system is mounted automatically at IPL time.

If you do not know which BPXPRMxx member is active, follow these steps to find out:

1. In the operations console, enter the following command to see which parmlib members are included in the parmlib concatenation on your system:

   D PARMLIB

2. Make a note of the BPXPRMxx member suffixes that you see.

3. To determine which BPXPRMxx member takes precedence, enter the following command:

   D OMVS

The output of this command should be similar to the following:

```
BPXO042I 04.01.03 DISPLAY OMVS 391
OMVS 000F ACTIVE OMVS=(ST,3T)
```

In this example, the member BPXPRMST takes precedence. If BPXPRMST is not present in the concatenation, member BPXPRM3T is used.

Procedure

Add a MOUNT command for the z/OSMF user file system to your currently active BPXPRMxx parmlib member. For example:

On a z/OS V2R3 system with the PTF for APAR PI92211 installed:

```
MOUNT FILESYSTEM('IZU.SIZUUSRD') TYPE(ZFS) MODE(RDWR)
MOUNTPOINT('/global/zosmf') PARM('AGGRGROW') UNMOUNT
```

On a z/OS V2R2 or V2R3 system without PTF for APAR PI92211 installed:

```
MOUNT FILESYSTEM('IZU.SIZUUSRD') TYPE(ZFS) MODE(RDWR)
MOUNTPOINT('/var/zosmf') PARM('AGGRGROW') UNMOUNT
```

Results

The BPXPRMxx member is updated. At the next system IPL, the following message is issued to indicate that the z/OSMF file system is mounted automatically.

```
BPXF013I FILE SYSTEM IZU.SIZUUSRD WAS SUCCESSFULLY MOUNTED.
```

Adding the required REST services

You must enable a set of z/OSMF REST services for the Zowe framework.

The following system changes are described in this topic:

- Enabling the z/OSMF JOB REST services
- Enabling the TSO REST services on page 65
- Enabling the z/OSMF data set and file REST services
- Enabling the z/OSMF Workflow REST services and Workflows task UI

Enabling the z/OSMF JOB REST services

The Zowe framework requires that you enable the z/OSMF JOB REST services, as described in this topic.
Procedure

None

Results

To verify if the z/OSMF JOB REST services are enabled, open a web browser to our z/OS system (host name and port) and add the following REST call to the URL:

GET /zosmf/restjobs/jobs

The result is a list of the jobs that are owned by your user ID. For more information about the z/OSMF JOB REST services, see z/OSMF Programming Guide.

Common errors

Review the following messages and the corresponding resolutions as needed:

Symptom 1

401 Unauthorized

Cause

The user ID is not connected to IZUADMIN or IZUUSER.

Resolution

Connect your user ID to IZUADMIN or IZUUSER.

Symptom 2

HTTP/1.1 500 Internal Server Error {
"rc":16,"reason":-1,"stack":"JesException: CATEGORY_CIM rc=16 reason=-1 cause=com.ibm.zoszmf.util.eis.EisConnectionException: IZUG911I: Connection to "http://null:5988" cannot be established, or was lost and cannot be re-established using protocol "CIM"......Caused by: WBEMException: CIM_ERR_FAILED (JNI Exception type CannotConnectException:
Cannot connect to local CIM server.
Connection failed.)

Cause

For JES2, you may have performed one of the following "Modify" operations: Hold a job, Release a job, Change the job class, Cancel a job, Delete a job (Cancel a job and purge its output), or you are running JES3 without configuring CIM Server.

Resolution

If you are running JES2, you can use synchronous support for job modify operations which does not required CIM. If you are running JES3, follow the CIM setup instructions to configure CIM on your system.

Enabling the TSO REST services

The Zowe framework requires that you enable the TSO REST services, as described in this topic.

Before you begin

Ensure that the common event adapter component (CEA) of z/OS is running in full function mode.

1. To check if the CEA address space is active, enter the following command:

D A,CEA

1. If not, start CEA in full function mode. For detailed instructions, see System prerequisites for the CEA TSO/E address space services.

2. To verify that CEA is running in full function mode, enter the following command:

F CEA,D

The output should look like the following:

CEA0004I COMMON EVENT ADAPTER 399
Procedure

1. If you run z/OS V2R2 and V2R3, download job IZUTSSEC in the sample jobs package and upload this Job to z/OS. If you run z/OS V2R4, locate job IZUTSSEC at SYS1.SAMPLIB.
2. Review and edit job IZUTSSEC before you submit. You can review the IZUTSSEC section below for more details.
3. Submit IZUTSSEC as a batch job on your z/OS system.

IZUTSSEC

IBM provides a set of jobs in SYS1.SAMPLIB with sample RACF commands to help with your z/OSMF configuration and its prerequisites. The IZUTSSEC job represents the authorizations that are needed for the z/OSMF TSO/E address space service. Your security administrator can edit and run the job. Generally, your z/OSMF user ID requires the same authorizations for using the TSO/E address space services as when you perform these operations through a TSO/E session on the z/OS system. For example, to start an application in a TSO/E address space requires that your user ID be authorized to operate that application. In addition, to use TSO/E address space services, you must have:

- READ access to the account resource in class ACCTNUM, where account is the value specified in the COMMON_TSO ACCT option in parmlib.
- READ access to the CEA.CEATSO.TSOREQUEST resource in class SERVAUTH.
- READ access to the proc resource in class TSOPROC, where proc is the value specified with the COMMON_TSO PROC option in parmlib.
- READ access to the <SAF_PREFIX>*.izuUsers profile in the EJBROLE class. Or, at a minimum, READ access to the <SAF_PREFIX>.IzuManagementFacilityTsoServices.izuUsers resource name in the EJBROLE class. You must also ensure that the z/OSMF started task user ID, which is IZUSVR by default, has READ access to the CEA.CEATSO.TSOREQUEST resource in class SERVAUTH. To create a TSO/E address space on a remote system, you require the following authorizations:
- You must be authorized to the SAF resource profile that controls the ability to send data to the remote system (systemname), as indicated: CEA.CEATSO.FLOW.systemname
- To flow data between different systems in the sysplex, you must be authorized to do so by your external security manager, such as a RACF database with sysplex-wide scope. For example, to flow data between System A and System B, you must be permitted to the following resource profiles:
  - CEA.CEATSO.FLOW.SYSTEMA
  - CEA.CEATSO.FLOW.SYSTEMB

Results
The IZUTSSEC job should complete with return code 0000.

Enabling the z/OSMF data set and file REST services
The Zowe framework requires that you enable the z/OSMF data set and file REST services.

Before you begin

1. Ensure that the message queue size is set to a large enough value. It is recommended that you specify an IPCMSGQBYTES value of at least 20971520 (20M) in BPXPRMxx.

   Issue command D OMVS,O to see the current value of IPCMSGQBYTES, if it is not large enough, use the SETOMVS command to set a large value. To set this value dynamically, you can enter the following operator command:

   SETOMVS IPCMSGQBYTES=20971520

2. Ensure that the TSO REST services are enabled.
3. Ensure that IZUFPROC is in your JES concatenation.
4. Ensure that your user ID has a TSO segment defined. To do so, enter the following command from TSO/E command prompt:

   LU userid TSO

Where *userid* is your z/OS user ID.

The output from this command must include the section called **TSO information**, as shown in the following example:

   TSO LU ZOSMFAD TSO NORACF
   4:57:17 AM: USER=ZOSMFAD
   TSO INFORMATION
   ---------------
   ACCTNUM= 123412345
   PROC= OMVSPROC
   SIZE= 02096128
   MAXSIZE= 00000000
   USERDATA= 0000
   ***

**Procedure**

1. If you run z/OS V2R2 and V2R3, download job IZURFSEC in the sample jobs package and upload it to z/OS. If you run z/OS V2R4, locate job IZURFSEC at **SYS1.SAMPLIB**.

2. Copy the job.

3. Examine the contents of the job.

4. Modify the contents as needed so that the job will run on your system.

5. From the TSO/E command line, run the IZURFSEC job.

**Results**

Ensure that the IZURFSEC job completes with return code **0000**.

To verify if this setup is complete, try issuing a REST service. See the example in **List data sets** in the z/OSMF programming guide.

**Common errors**

Review the following messages and the corresponding resolutions as needed:

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>REST API doesn't return expected data with rc=12, rsn=3, message: message queue size &quot;SIZE&quot; is less than minimum: 20M</td>
<td>The message queue size for CEA is too small.</td>
<td>Ensure that the message queue size is set to a large enough value. It is recommended that you specify an IPCMSGQBYTES value of at least 20971520 (20M) in BPXPRMx.</td>
</tr>
</tbody>
</table>

**Enabling the z/OSMF Workflow REST services and Workflows task UI**

The Zowe framework requires that you enable the z/OSMF Workflow REST services and Workflows task UI.
Before you begin

1. Ensure that the JOB REST services are enabled.
2. Ensure that the TSO REST services are enabled.
3. Ensure that the dataset and file REST services are enabled.

Procedure

1. If you run z/OS V2R2 and V2R3, download job IZUWFSEC in the sample jobs package and upload this job to z/OS. If you run z/OS V2R4, locate job IZUWFSEC at SYS1.SAMPLIB.
2. Copy the job.
3. Examine the contents of the job.
4. Modify the contents as needed so that the job will run on your system.
5. From the TSO/E command line, run the IZUWFSEC job.

Results

Ensure the IZUWFSEC job completes with return code 0000.

To verify, log on to z/OSMF (or refresh it) and verify that the Workflows task appears in the z/OSMF UI.

At this point, you have completed the setup of z/OSMF Lite.

Optionally, you can add more users to z/OSMF, as described in Appendix C. Adding more users to z/OSMF.

Troubleshooting problems

This section provides tips and techniques for troubleshooting problems you might encounter when creating a z/OSMF Lite configuration. For other types of problems that might occur, see z/OSMF Configuration Guide.

Common problems and scenarios

This section discusses troubleshooting topics, procedures, and tools for recovering from a set of known issues.

System setup requirements not met

This document assumes that the following is true of the z/OS host system:

- Port 443 is available for use. To check this, issue either TSO command NETSTAT SOCKET or TSO command NETSTAT BYTE to determine if the port is being used.
- The system host name is unique and maps to the system on which z/OSMF Lite is being installed. To retrieve this value, enter either "hostname" z/OS UNIX command or TSO command "HOMETEST". If your system uses another method of assigning the system name, such as a multi-home stack, dynamic VIPA, or System Director, see z/OSMF Configuration Guide.
- The global mount point exists. On a z/OS 2.3 system, the system includes this directory by default. On a z/OS 2.2 system, you must create the global directory at the following location: /global/zosmf/.

If you find that a different value is used on your z/OS system, you can edit the IZUPRMxx parmlib member to specify the correct setting. For details, see Appendix A. Creating an IZUPRMxx parmlib member on page 69.

Tools and techniques for troubleshooting

For information about working with z/OSMF log files, see z/OSMF Configuration Guide.

Common messages

| ICH420I PROGRAM CELQLIB FROM LIBRARY CEE.SCEERUN2 CAUSED THE ENVIRONMENT TO BECOME UNCONTROLLED. |
| BPXP014I ENVIRONMENT MUST BE CONTROLLED FOR DAEMON (BPX.DAEMON) PROCESSING. |

If you see above error messages, check if your IZUANG0 procedure is up to date.

For descriptions of all the z/OSMF messages, see z/OSMF messages in IBM Knowledge Center.
Appendix A. Creating an IZUPRMxx parmlib member

If z/OSMF requires customization, you can modify the applicable settings by using the IZUPRMxx parmlib member. To see a sample member, locate the IZUPRM00 member in the SYS1.SAMPLIB data set. IZUPRM00 contains settings that match the z/OSMF defaults.

Using IZUPRM00 as a model, you can create a customized IZUPRMxx parmlib member for your environment and copy it to SYS1.PARMLIB to override the defaults.

The following IZUPRMxx settings are required for the z/OSMF nucleus:

- HOSTNAME
- HTTP_SSL_PORT
- JAVA_HOME.

The following setting is needed for the TSO/E REST services:

- COMMON_TSO ACCT(IZUACCT) REGION(50000) PROC(IZUFPROC)

Descriptions of these settings are provided in the table below. For complete details about the IZUPRMxx settings and the proper syntax for updating the member, see z/OSMF Configuration Guide.

If you change values in the IZUPRMxx member, you might need to customize the started procedure IZUSVR1, accordingly. For details, see Appendix B. Modifying IZUSVR1 settings on page 70.

To create an IZUPRMxx parmlib member, follow these steps:

1. Copy the sample parmlib member into the desired parmlib data set with the desired suffix.
2. Update the parmlib member as needed.
3. Specify the IZUPRMxx parmlib member or members that you want the system to use on the IZU parameter of IEASYSxx. Or, code a value for IZUPRM= in the IZUSVR1 started procedure. If you specify both IZU= in IEASYSxx and IZUPARM= in IZUSVR1, the system uses the IZUPRM= value you specify in the started procedure.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Purpose</th>
<th>Rules</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>HOSTNAME(hostname)</td>
<td>Specifies the host name, as defined by DNS, where the z/OSMF server is located. To use the local host name, enter asterisk (*), which is equivalent to @HOSTNAME from previous releases. If you plan to use z/OSMF in a multisystem sysplex, IBM recommends using a dynamic virtual IP address (DVIPA) that resolves to the correct IP address if the z/OSMF server is moved to a different system.</td>
<td>Must be a valid TCP/IP HOSTNAME or an asterisk (*).</td>
<td>Default: *</td>
</tr>
</tbody>
</table>
### Setting | Purpose | Rules | Default
--- | --- | --- | ---
HTTP_SSL_PORT(nnn) | Identifies the port number that is associated with the z/OSMF server. This port is used for SSL encrypted traffic from your z/OSMF configuration. The default value, 443, follows the Internet Engineering Task Force (IETF) standard. **Note:** By default, the z/OSMF server uses the SSL protocol SSL_TLSv2 for secure TCP/IP communications. As a result, the server can accept incoming connections that use SSL V3.0 and the TLS 1.0, 1.1 and 1.2 protocols. | Must be a valid TCP/IP port number. Value range: 1 - 65535 (up to 5 digits) | Default: 443

**COMMON_TSO**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Purpose</th>
<th>Rules</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCT(account-number)</td>
<td>Specifies values for the TSO/E logon procedure that is used internally for various z/OSMF activities and by the Workflows task.</td>
<td>The valid ranges for each value are described in z/OSMF Configuration Guide.</td>
<td>Default: 443 ACCT(IZUACCT) REGION(50000) PROC(IZUFPROC)</td>
</tr>
<tr>
<td>REGION(region-size)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>PROC(proc-name)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**USER_DIR=filepath**

z/OSMF data directory path. By default, the z/OSMF data directory is located in /global/zosmf. If you want to use a different path for the z/OSMF data directory, specify that value here, for example: USER_DIR=/the/new/config/dir. | Must be a valid z/OS UNIX path name. | Default: /global/zosmf/

### Appendix B. Modifying IZUSVR1 settings

You might need to customize the started procedure IZUSVR1 for z/OSMF Lite.

To modify the IZUSVR1 settings, follow these steps:

1. Make a copy
2. Apply your changes
3. Store your copy in PROCLIB.

### Setting | Purpose | Rules | Default
--- | --- | --- | ---
WLPDIR='directory-path' | WebSphere Liberty server code path. | The directory path must: Be a valid z/OS UNIX path name Be a full or absolute path name Be enclosed in quotation marks Begin with a forward slash ('/'). | Default: /usr/lpp/zosmf/liberty |
### Appendix C. Adding more users to z/OSMF

Your security administrator can authorize more users to z/OSMF. Simply connect the required user IDs to the z/OSMF administrator group (IZUADMIN). This group is permitted to a default set of z/OSMF resources (tasks and services). For the specific group permissions, see Appendix A in *z/OSMF Configuration Guide*.

You can create more user groups as needed, for example, one group per z/OSMF task.

**Before you Begin**

Collect the z/OS user IDs that you want to add.

**Procedure**

1. On an RACF system, enter the CONNECT command for the user IDs to be granted authorization to z/OSMF resources:

   ```
   CONNECT userid GROUP(IZUADMIN)
   ```

   **Results**

   The user IDs can now access z/OSMF.

### Installing Zowe z/OS components

#### Installation roadmap

To install Zowe™ on z/OS, there are two parts. The first part is the Zowe runtime that consists of three components: Zowe Application Framework, z/OS Explorer Services, and Zowe API Mediation Layer. The second part is the Zowe Cross Memory Server. This is an authorized server application that provides privileged services to Zowe in a secure manner.

Review the installation diagram and the introduction in this topic to see the general installation sequence and the most important tasks that are to be performed during installation and configuration. You can click each step on the diagram for detailed instructions.
Stage 1: Plan and prepare

Plan and prepare for the installation

Stage 2: Install the Zowe runtime

Start the installation

Ensure system requirements are met

What is your preferred installation method?

SMP/E build

Download the Zowe SMP/E build

Install the Zowe SMP/E build

Convenience build

Download the convenience build

Verify, transfer, and expand the PAX file on z/OS

Install the Zowe runtime
(Script: zowe-install.sh)

Installation Output:
- A zFS folder containing unconfigured Zowe runtime <RUNTIME_DIR>
- A SAMPLIB library $ZWESAMP containing sample members
- A load library $ZWEAUTH containing load modules

Stage 3: Configure the Zowe runtime

(One-time setup per z/OS environment)
Configure the z/OS system for Zowe
(JCL: ZWESECUR)

(One-time setup per z/OS environment)
Create the Zowe certificates keystore directory
(Script: zowe-setup-certificates.sh)

Create and configure the Zowe instance directory
(Script: zowe-configure-instance.sh)

(Required for Zowe Desktop)
Install and configure the Zowe cross memory server (ZWESISTC)
(Script: zowe-install-xmem.sh)

Install the Zowe started task (ZWESVSTC)
(Script: zowe-install-proc.sh)

Stage 4: Verify the installation

Verify that Zowe is installed and configured correctly
Stage 1: Plan and prepare

Before you start the installation, review the information on hardware and software requirements and other considerations. See Introduction on page 48 for details.

Stage 2: Install the Zowe runtime

1. Ensure that the software requirements are met. The prerequisites are described in System requirements on page 48.
2. Choose the method of installing Zowe on z/OS.

   The Zowe z/OS binaries are distributed in the following formats. They contain the same contents but you install them by using different methods. You can choose which method to use depending on your needs.
   - **Convenience build**
     The Zowe z/OS binaries are packaged as a PAX file. You install this build by running shell script within a UNIX System Services (USS) shell. Convenience builds are full product installs.
   - **SMP/E build**
     The Zowe z/OS binaries are packaged as the following files that you can download. You install this build through SMP/E.
     - A pax.Z file, which contains an archive (compressed copy) of the FMIDs to be installed.
     - A readme file, which contains a sample job to decompress the pax.Z file, transform it into a format that SMP/E can process, and invoke SMP/E to extract and expand the compressed SMP/E input data sets.

   While the procedure to obtain and install the convenience build or SMP/E build are different, the procedure to configure a Zowe runtime are the same irrespective of how the build is obtained and installed.
3. Obtain and install the Zowe build.
   - For how to obtain the convenience build and install it, see Installing Zowe runtime from a convenience build on page 74.
   - For how to obtain the SMP/E build and install it, see Installing Zowe SMP/E on page 77.

After successful installation of either a convenience build or an SMP/E build, there will be a zFS folder that contains the unconfigured Zowe runtime `<RUNTIME_DIR>`, a SAMPLIB library `SZWESAMP` that contains sample members, and a load library `SZWEAUTH` that contains load modules. The steps to prepare the z/OS environment to launch Zowe are the same irrespective of the installation method.

Stage 3: Configure the Zowe runtime

1. Configure the z/OS security manager to prepare for launching the Zowe started tasks. For instructions, see Configuring the z/OS system for Zowe on page 96.

   A SAMPLIB JCL member `ZWESECUR` is provided to assist with the configuration. You can submit the `ZWESECUR` JCL member as-is or customize it depending on site preferences.

   If Zowe has already been launched on the z/OS system from a previous release of Version 1.8 or later, then you are applying a newer Zowe build. You can skip this security configuration step unless told otherwise in the release documentation.
2. Configure the Zowe certificates keystore and truststore directory. For instructions, see Configuring Zowe certificates on page 102.

   If you have already created a keystore directory from a previous release of Version 1.8 or later, then you may reuse the existing keystore directory.

   The Zowe keystore directory contains the key used by the Zowe desktop and the Zowe API mediation layer to secure its TLS communication with clients (such as web browsers or REST AI clients). The keystore directory also has a truststore where public keys of any servers that Zowe communicates to (such as z/OSMF) are held.

   A keystore directory needs to be created for a Zowe instance to be launched successfully, and a keystore directory can be shared between Zowe instances and between Zowe runtimes, including between different Zowe releases, unless specified otherwise in the release documentation.
3. Create and customize an instance directory that contains configuration data required to launch a Zowe runtime and is where log files are stored. For instructions, see Creating and configuring the Zowe instance directory on page 104.

A single Zowe runtime can be launched multiple times from different instance directories, each specifying different port ranges, applications to include at start-up, paths of associated runtimes (Java, Node, z/OSMF).

Next, you will install and configure the Zowe started tasks. Zowe has two high level started tasks: ZWESVSTC that launches the Zowe desktop and API mediation layer address spaces, and ZWESISTC that is a cross memory server that runs all of the APF-authorized code. The JCLs for the tasks are included in the PDS SAMPLIB SZWESAMP installed by Zowe and the load modules for the cross memory server are included in the PDS load library SZWEAUTH.

Note By default, the API Mediation Layer rejects encoded slashes in the URL path of the request. Not allowing encoded slashes is the recommended configuration. If you are onboarding applications which expose endpoints expecting encoded slashes, you need to configure the API Mediation Layer to allow this pattern by performing the following steps:

a. Open the file <Zowe install directory>/components/api-mediation/bin/start.sh.
b. Find the line that contains the -Dapiml.service.allowEncodedSlashes=false parameter and set the value to true:
c. Restart Zowe™. Requests with encoded slashes will now be passed to onboarded services.

4. (Only required for launching the Zowe desktop) Configure the ZWESISTC cross memory server and install the load libraries. For instructions, see Installing and configuring the Zowe cross memory server (ZWESISTC) on page 108.

The cross memory server is only required if you want to use the Zowe desktop. The cross memory server is not used by API Mediation Layer. If you want to use Zowe API Mediation Layer only, you can skip this step.

Which components of Zowe are started is determined by the LAUNCH_COMPONENT_GROUPS value in the instance.env file in the Zowe instance directory, see Component groups on page 105.

5. Configure the ZWESVSTC started task. For instructions, see Installing the Zowe started task (ZWESVSTC) on page 111.

Stage 4: Verify the installation

Verify that Zowe is installed correctly on z/OS. See Verifying Zowe installation on z/OS on page 113.

Looking for troubleshooting help?

If you encounter unexpected behavior when installing or verifying the Zowe runtime on z/OS, see the Troubleshooting on page 288 section for tips.

Installing Zowe runtime from a convenience build

You install the Zowe™ convenience build by running shell script within a UNIX System Services (USS) shell.

Obtaining and preparing the convenience build

The Zowe installation file for Zowe z/OS components is distributed as a PAX file that contains the runtimes and the scripts to install and launch the z/OS runtime. For each release, there is a PAX file named zowe-V.v.p.pax, where

- \( V \) indicates the Major Version
- \( v \) indicates the Minor Version
- \( p \) indicates the Patch number

The numbers are incremented each time a release is created so the higher the numbers, the later the release. For more information on the Zowe release number, see Understanding the Zowe release on page 288.
To download the PAX file, open your web browser and click the **Zowe z/OS Components** button on the **Zowe Download** website to save it to a folder on your desktop. After you download the PAX file, follow the instructions to verify the PAX file and prepare it to install the Zowe runtime.

**Follow these steps:**

1. Verify the integrity of the PAX file to ensure that the file you download is officially distributed by the Zowe project.

   Follow the instructions in the **Verify Hash and Signature of Zowe Binary** section on the post-download page [https://d1xozlojgf8voe.cloudfront.net/post_download.html?version=V.v.p](https://d1xozlojgf8voe.cloudfront.net/post_download.html?version=V.v.p) after you download the official build. For example, the post-download page for Version 1.4.0 is [https://d1xozlojgf8voe.cloudfront.net/post_download.html?version=1.4.0](https://d1xozlojgf8voe.cloudfront.net/post_download.html?version=1.4.0).

2. Transfer the PAX file to z/OS.

   **Follow these steps:**
   a. Open a terminal in Mac OS/Linux, or command prompt in Windows OS, and navigate to the directory where you downloaded the Zowe PAX file.
   b. Connect to z/OS using SFTP. Issue the following command:

   ```bash
   sftp <userID@ip.of.zos.box>
   ```

   If SFTP is not available or if you prefer to use FTP, you can issue the following command instead:

   ```bash
   ftp <userID@ip.of.zos.box>
   ```

   **Note:** When you use FTP, switch to binary file transfer mode by issuing the following command:

   ```bash
   bin
   ```

c. Navigate to the target directory that you want to transfer the Zowe PAX file into on z/OS.

   **Note:** After you connect to z/OS and enter your password, you enter the UNIX file system. The following commands are useful:
   - To see what directory you are in, type `pwd`.
   - To switch directory, type `cd`.
   - To list the contents of a directory, type `ls`.
   - To create a directory, type `mkdir`.

d. When you are in the directory you want to transfer the Zowe PAX file into, issue the following command:

   ```bash
   put <zowe-V.v.p>.pax
   ```

   Where `zowe-V.v.p` is a variable that indicates the name of the PAX file you downloaded.

   **Note:** When your terminal is connected to z/OS through FTP or SFTP, you can prepend commands with `l` to have them issued against your desktop. To list the contents of a directory on your desktop, type `lls` where `ls` lists contents of a directory on z/OS.

3. When the PAX file is transferred, expand the PAX file by issuing the following command in an SSH session:

   ```bash
   pax -ppx -tf <zowe-V.v.p>.pax
   ```

   Where `zowe-V.v.p` is a variable that indicates the name of the PAX file you downloaded.

   This will expand to a file structure.

   ```bash
   /bin
   /files
   /install
   ```
Installing the Zowe runtime

The first installation step is to create a USS folder that contains the Zowe runtime artifacts. This is known as the \(<RUNTIME\_DIR>\).

**Step 1: Locate the install directory**

Navigate to the directory where the installation archive is extracted. Locate the /install directory.

```
navigate to /install
```

**Step 2: Choose a runtime USS folder**

For Zowe to execute, it must be installed into a runtime directory or \(<RUNTIME\_DIR>\). This directory will be created during the installation process and the user who performs the installation must have write permission for the installation to succeed.

If you are installing an upgrade of Zowe, the runtime directory used should be the existing \(<RUNTIME\_DIR>\) of where the previous Zowe was installed. Upgrading Zowe is only supported for Version 1.8 or later.

For an enterprise installation of Zowe, a \(<RUNTIME\_DIR>\) could be \(/usr/lpp/zowe/v1\). For users who test Zowe for themselves, it could be \(~zowe/v1\).

**Step 3: Choose a dataset HLQ for the SAMPLIB and LOADLIB**

During installation, two PDS data sets are created: the \(SZWESAMP\) data set and the \(SZWEAUTH\) data set. These are not used at runtime and there is a further step needed to promote these to the z/OS execution environment but they contain required JCL and load modules.

You must know the \(<DATA\_SET\_PREFIX>\) into which to create the \(SZWESAMP\) and the \(SZWEAUTH\) PDS data sets. If a \(<DATA\_SET\_PREFIX>\) of \(OPENSRC.ZWE\) is specified, the PDS data sets \(OPENSRC.ZWE.SZWESAMP\) and \(OPENSRC.ZWE.SZWEAUTH\) will be created during installation. The storage requirements are included here.

<table>
<thead>
<tr>
<th>Library</th>
<th>Member name</th>
<th>Type</th>

<td>Started task JCL for the cross memory Auxiliary server</td>
</tr>
<tr>
<td>ZWESIPRG</td>
<td>Console commands to APF authorize the cross memory server load library</td>
</tr>
<tr>
<td>ZWESISCH</td>
<td>PPT entries required by Cross memory server and its Auxiliary address spaces to run in Key(4)</td>
</tr>
</tbody>
</table>

The **SZWEAUTH** data set is a load library containing the following members.

<table>
<thead>
<tr>
<th>Member name</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZWESIS01</td>
<td>Load module for the cross memory server</td>
</tr>
<tr>
<td>ZWESAUXX</td>
<td>Load module for the cross memory server’s auxiliary address space</td>
</tr>
</tbody>
</table>

**Step 3a: Choose a log directory (optional)**

By default during install and configure various logs will be created in `/global/zowe/logs`, if it is writable, or `~/.zowe/logs`. If neither of these directories exists, or is writable by the installing user, or you wish to override and provide your own directory as the place that logs go you can specify this with the `-l` parameter.

**Step 4: Install the Zowe runtime**

You install the Zowe runtime by executing the `zowe-install.sh` script passing in the arguments for the USS runtime directory and the prefix for the SAMPLIB and loadlib PDS members.

```
zowe-install.sh -i <RUNTIME_DIR> -h <DATASET_PREFIX> [-l <LOG_DIR>]
```

In this documentation, the steps of creating the runtime directory and configuring the runtime directory are described separately. The configuration step is the same for a Zowe runtime whether it is installed from a convenience build or from an SMP/E distribution.

**Next steps**

For a z/OS system where you install Zowe 1.8 or later for the first time, follow the instructions in *Stage 3: Configure the Zowe runtime* on page 73 that describes how to *Configuring the z/OS system for Zowe* on page 96 and *Configuring Zowe certificates* on page 102.

If you have previously installed Zowe 1.8 or later, then you already have an instance directory that needs to be updated. If you have not installed Zowe 1.8 or later before, you will need to create an instance directory to be able to launch Zowe. For instructions, see *Creating and configuring the Zowe instance directory* on page 104.

Zowe has two started tasks that need to be installed and configured ready to be started. These are the Zowe server, see *Installing the Zowe started task (ZWESVSTC)* on page 111 and the Zowe cross memory server, see *Installing and configuring the Zowe cross memory server (ZWESISSTC)* on page 108.

**Installing Zowe SMP/E**

**Contents**

- Introduction on page 78
  - Zowe description on page 79
  - Zowe FMIDs on page 79
Introduction

This program directory is intended for system programmers who are responsible for program installation and maintenance. It contains information about the material and procedures associated with the installation of Zowe Open Source Project (Base). This publication refers to Zowe Open Source Project (Base) as Zowe.
The Program Directory contains the following sections:

- **Program materials on page 79** identifies the basic program materials and documentation for Zowe.
- **Program support on page 79** describes the support available for Zowe.
- **Program and service level information on page 80** lists the APARs (program level) and PTFs (service level) that have been incorporated into Zowe.
- **Installation requirements and considerations on page 80** identifies the resources and considerations that are required for installing and using Zowe.
- **Installation instructions on page 84** provides detailed installation instructions for Zowe. It also describes the procedures for activating the functions of Zowe, or refers to appropriate publications.

**Zowe description**

Zowe™ is an open source project created to host technologies that benefit the Z platform. It is a sub-project of Open Mainframe Project which is part of the Linux Foundation. More information about Zowe is available at https://zowe.org.

**Zowe FMIDs**

Zowe consists of the following FMIDs:

- AZWE001

**Program materials**

Basic Machine-Readable Materials are materials that are supplied under the base license and are required for the use of the product.

**Basic machine-readable material**

The distribution medium for this program is via downloadable files. This program is in SMP/E RELFILE format and is installed using SMP/E. See **Installation instructions on page 84** for more information about how to install the program.

**Program publications**

You can obtain the Zowe documentation from the Zowe doc site at https://docs.zowe.org/. No optional publications are provided for Zowe.

**Program source materials**

No program source materials or viewable program listings are provided for Zowe in the SMP/E installation package. However, program source materials can be downloaded from the Zowe GitHub repositories at https://github.com/zowe/.

**Publications useful during installation**

Publications listed below are helpful during the installation of Zowe.

<table>
<thead>
<tr>
<th>Publication Title</th>
<th>Form Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM SMP/E for z/OS User's Guide</td>
<td>SA23-2277</td>
</tr>
<tr>
<td>IBM SMP/E for z/OS Commands</td>
<td>SA23-2275</td>
</tr>
<tr>
<td>IBM SMP/E for z/OS Reference</td>
<td>SA23-2276</td>
</tr>
<tr>
<td>IBM SMP/E for z/OS Messages, Codes, and Diagnosis</td>
<td>GA32-0883</td>
</tr>
</tbody>
</table>

These and other publications can be obtained from https://www.ibm.com/shop/publications/order.

**Program support**

This section describes the support available for Zowe.
Because this is an alpha release of the Zowe FMID package for early testing and adoption, no formal support is offered. Support is available through the Zowe community. See Community Engagement for details. Slack is the preferred interaction channel.

Additional support may be available through other entities outside of the Open Mainframe Project and Linux Foundation which offers no warranty and provides the package under the terms of the EPL v2.0 license.

Statement of support procedures

Report any problems which you feel might be an error in the product materials to the Zowe community via the Zowe GitHub community repo at https://github.com/zowe/community/issues/new/choose. You may be asked to gather and submit additional diagnostics to assist the Zowe Community for analysis and resolution.

Program and service level information

This section identifies the program and relevant service levels of Zowe. The program level refers to the APAR fixes that have been incorporated into the program. The service level refers to the PTFs that have been incorporated into the program.

Program level information

All issues of previous releases of Zowe that were resolved before August 2019 have been incorporated into this packaging of Zowe.

Service level information

Since this is the first release of the SMP/E package, no PTFs have been created.

Installation requirements and considerations

The following sections identify the system requirements for installing and activating Zowe. The following terminology is used:

- Driving System: the system on which SMP/E is executed to install the program.
- Target system: the system on which the program is configured and run.

Use separate driving and target systems in the following situations:

- When you install a new level of a product that is already installed, the new level of the product will replace the old one. By installing the new level onto a separate target system, you can test the new level and keep the old one in production at the same time.
- When you install a product that shares libraries or load modules with other products, the installation can disrupt the other products. By installing the product onto a separate target system, you can assess these impacts without disrupting your production system.

Driving system requirements

This section describes the environment of the driving system required to install Zowe.

Driving system machine requirements

The driving system can be run in any hardware environment that supports the required software.

Driving system programming requirements

<table>
<thead>
<tr>
<th>Program Number</th>
<th>Product Name</th>
<th>Minimum VRM</th>
<th>Minimum Service Level will satisfy these APARs</th>
<th>Included in the shipped product?</th>
</tr>
</thead>
<tbody>
<tr>
<td>5650-ZOS</td>
<td>z/OS</td>
<td>V2.2.0 or later</td>
<td>N/A</td>
<td>No</td>
</tr>
</tbody>
</table>

Notes:

- SMP/E is a requirement for Installation and is an element of z/OS but can also be ordered as a separate product, 5655-G44, minimally V03.06.00.
• Installation might require migration to a new z/OS release to be service supported. See https://www-01.ibm.com/software/support/lifecycle/index_z.html.

Zowe is installed into a file system, either HFS or zFS. Before installing Zowe, you must ensure that the target system file system data sets are available for processing on the driving system. OMVS must be active on the driving system and the target system file data sets must be mounted on the driving system.

If you plan to install Zowe in a zFS file system, this requires that zFS be active on the driving system. Information on activating and using zFS can be found in z/OS Distributed File Service zSeries File System Administration (SC24-5989).

**Target system requirements**

This section describes the environment of the target system required to install and use Zowe.

Zowe installs in the z/OS (Z038) SREL.

**Target system machine requirements**

The target system can run in any hardware environment that supports the required software.

**Target system programming requirements**

**Installation requisites**

Installation requisites identify products that are required and must be present on the system or products that are not required but should be present on the system for the successful installation of Zowe.

Mandatory installation requisites identify products that are required on the system for the successful installation of Zowe. These products are specified as PREs or REQs.

*Zowe has no mandatory installation requisites.*

Conditional installation requisites identify products that are not required for successful installation of Zowe but can resolve such things as certain warning messages at installation time. These products are specified as IF REQs.

*Zowe has no conditional installation requisites.*

**Operational requisites**

Operational requisites are products that are required and must be present on the system, or, products that are not required but should be present on the system for Zowe to operate all or part of its functions.

Mandatory operational requisites identify products that are required for this product to operate its basic functions. The following table lists the target system mandatory operational requisites for Zowe.

<table>
<thead>
<tr>
<th>Program Number</th>
<th>Product Name and Minimum VRM/Service Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>5650-ZOS</td>
<td>IBM z/OS Management Facility V2.2.0 or higher</td>
</tr>
<tr>
<td>5655-SDK</td>
<td>IBM SDK for Node.js - z/OS V8.16.0 or higher</td>
</tr>
<tr>
<td>5655-DGH</td>
<td>IBM 64-bit SDK for z/OS Java Technology Edition V8.0.0</td>
</tr>
</tbody>
</table>

Conditional operational requisites identify products that are not required for Zowe to operate its basic functions but are required at run time for Zowe to operate specific functions. These products are specified as IF REQs. Zowe has no conditional operational requisites.

**Toleration/coexistence requisites**

Toleration/coexistence requisites identify products that must be present on sharing systems. These systems can be other systems in a multi-system environment (not necessarily Parallel Sysplex™), a shared DASD environment (such as test and production), or systems that reuse the same DASD environment at different time intervals.

Zowe has no toleration/coexistence requisites.

**Incompatibility (negative) requisites**
Negative requisites identify products that must not be installed on the same system as Zowe.
Zowe has no negative requisites.

**DASD storage requirements**

Zowe libraries can reside on all supported DASD types.

**Total DASD space required by Zowe**

<table>
<thead>
<tr>
<th>Library Type</th>
<th>Total Space Required in 3390 Trks</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target</td>
<td>30 Tracks</td>
<td>/</td>
</tr>
<tr>
<td>Distribution</td>
<td>12030 Tracks</td>
<td>/</td>
</tr>
<tr>
<td>File System(s)</td>
<td>9000 Tracks</td>
<td>/</td>
</tr>
<tr>
<td>Web Download</td>
<td>26111 Tracks</td>
<td>These are temporary data sets, which can be removed after the SMP/E install.</td>
</tr>
</tbody>
</table>

**Notes:**

1. For non-RECFM U data sets, we recommend using system-determined block sizes for efficient DASD utilization. For RECFM U data sets, we recommend using a block size of 32760, which is most efficient from the performance and DASD utilization perspective.

2. Abbreviations used for data set types are shown as follows.
   - **U** - Unique data set, allocated by this product and used by only this product. This table provides all the required information to determine the correct storage for this data set. You do not need to refer to other tables or program directories for the data set size.
   - **S** - Shared data set, allocated by this product and used by this product and other products. To determine the correct storage needed for this data set, add the storage size given in this table to those given in other tables (perhaps in other program directories). If the data set already exists, it must have enough free space to accommodate the storage size given in this table.
   - **E** - Existing shared data set, used by this product and other products. This data set is not allocated by this product. To determine the correct storage for this data set, add the storage size given in this table to those given in other tables (perhaps in other program directories). If the data set already exists, it must have enough free space to accommodate the storage size given in this table.

If you currently have a previous release of Zowe installed in these libraries, the installation of this release will delete the old release and reclaim the space that was used by the old release and any service that had been installed. You can determine whether these libraries have enough space by deleting the old release with a dummy function, compressing the libraries, and comparing the space requirements with the free space in the libraries.

For more information about the names and sizes of the required data sets, see Allocate SMP/E target and distribution libraries.

3. Abbreviations used for the file system path type are as follows.
   - **N** - New path, created by this product.
   - **X** - Path created by this product, but might already exist from a previous release.
   - **P** - Previously existing path, created by another product.

4. All target and distribution libraries listed have the following attributes:
   - The default name of the data set can be changed.
   - The default block size of the data set can be changed.
   - The data set can be merged with another data set that has equivalent characteristics.
   - The data set can be either a PDS or a PDSE, with some exceptions. If the value in the "ORG" column specifies "PDS", the data set must be a PDS. If the value in "DIR Blks" column specifies "N/A", the data set must be a PDSE.
5. All target libraries listed have the following attributes:
   - These data sets can be SMS-managed, but they are not required to be SMS-managed.
   - These data sets are not required to reside on the IPL volume.
   - The values in the "Member Type" column are not necessarily the actual SMP/E element types that are identified in the SMPMCS.

6. All target libraries that are listed and contain load modules have the following attributes:
   - These data sets cannot be in the LPA, with some exceptions. If the value in the "Member Type" column specifies "LPA", it is advised to place the data set in the LPA.
   - These data sets can be in the LNKLST.
   - These data sets are not required to be APF-authorized, with some exceptions. If the value in the "Member Type" column specifies "APF", the data set must be APF-authorized.

### Storage requirements for SMP/E work data sets

<table>
<thead>
<tr>
<th>Library DDNAME</th>
<th>TYPE</th>
<th>ORG</th>
<th>RECFM</th>
<th>LRECL</th>
<th>No. of 3390 Trks</th>
<th>No. of DIR Blks</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMPWRK6</td>
<td>S</td>
<td>PDS</td>
<td>FB</td>
<td>80</td>
<td>(20,200)</td>
<td>50</td>
</tr>
<tr>
<td>SYSUT1</td>
<td>U</td>
<td>SEQ</td>
<td>--</td>
<td>--</td>
<td>(20,200)</td>
<td>0</td>
</tr>
</tbody>
</table>

In the table above, (20,200) specifies a primary allocation of 20 tracks, and a secondary allocation of 200 tracks.

### Storage requirements for SMP/E data sets

<table>
<thead>
<tr>
<th>Library DDNAME</th>
<th>TYPE</th>
<th>ORG</th>
<th>RECFM</th>
<th>LRECL</th>
<th>No. of 3390 Trks</th>
<th>No. of DIR Blks</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMPPTS</td>
<td>S</td>
<td>PDSE</td>
<td>FB</td>
<td>80</td>
<td>(12000,3000)</td>
<td>50</td>
</tr>
</tbody>
</table>

The following figures describe the target and distribution libraries and file system paths required to install Zowe. The storage requirements of Zowe must be added to the storage required by other programs that have data in the same library or path.

**Note:** Use the data in these tables to determine which libraries can be merged into common data sets. In addition, since some ALIAS names may not be unique, ensure that no naming conflicts will be introduced before merging libraries.

### Storage requirements for Zowe target libraries

**Note:** These target libraries are not required for the initial FMID install of Zowe SMP/E but will be required for subsequent SYSMODS so are included here for future reference.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Note: These are temporary data sets, which can be removed after the SMP/E installation.

**FMIDs deleted**

Installing Zowe might result in the deletion of other FMIDs.

To see which FMIDs will be deleted, examine the `+++VER` statement in the SMPMCS of the product. If you do not want to delete these FMIDs now, install Zowe into separate SMP/E target and distribution zones.

**Note:** These FMIDs are not automatically deleted from the Global Zone. If you want to delete these FMIDs from the Global Zone, use the SMP/E REJECT OFMID DELETEFMID command. See the SMP/E Commands book for details.

**Special considerations**

Zowe has no special considerations for the target system.

**Installation instructions**

This section describes the installation method and the step-by-step procedures to install and activate the functions of Zowe.

**Notes:**

- If you want to install Zowe into its own SMP/E environment, consult the SMP/E manuals for instructions on creating and initializing the SMPCSI and SMP/E control data sets.
- You can use the sample jobs that are provided to perform part or all of the installation tasks. The SMP/E jobs assume that all DDDEF entries that are required for SMP/E execution have been defined in appropriate zones.
- You can use the SMP/E dialogs instead of the sample jobs to accomplish the SMP/E installation steps.

**SMP/E considerations for installing Zowe**

Use the SMP/E RECEIVE, APPLY, and ACCEPT commands to install this release of Zowe.

**SMP/E options subentry values**

The recommended values for certain SMP/E CSI subentries are shown in the following table. Using values lower than the recommended values can result in failures in the installation. DSSPACE is a subentry in the GLOBAL options.
entry. PEMAX is a subentry of the GENERAL entry in the GLOBAL options entry. See the SMP/E manuals for instructions on updating the global zone.

<table>
<thead>
<tr>
<th>Subentry</th>
<th>Value</th>
<th>Comment</th>

<tr>
<td>PEMAX</td>
<td>SMP/E Default</td>
<td>IBM recommends using the SMP/E default for PEMAX.</td>
</tr>
</tbody>
</table>

**Overview of the installation steps**

Follow these high-level steps to download and install Zowe Open Source Project (Base).

1. Download the Zowe SMP/E package
2. Allocate file system to hold the download package on page 85
3. Upload the download package to the host on page 87
4. Extract and expand the compressed SMPMCS and RELFILEs on page 87
5. Sample installation jobs on page 89
6. Create SMP/E environment (optional)
7. Perform SMP/E RECEIVE
8. Allocate SMP/E target and distribution libraries
9. Allocate, create and mount ZSF files (Optional) on page 92
10. Allocate z/OS UNIX paths
11. Create DDDEF entries on page 93
12. Perform SMP/E APPLY
13. Perform SMP/E ACCEPT
14. Run REPORT CROSSZONE on page 95
15. Cleaning up obsolete data sets, paths, and DDDEFs on page 95

**Download the Zowe SMP/E package**

To download the Zowe SMP/E package, open your web browser and go to the Zowe Download website. Click the Zowe SMP/E FMID AZWE001 button to save the file to a folder on your desktop.

You will receive one ZIP package on your desktop. You can extract the following files from the package.

- **AZWE001.pax.Z (binary)**
  The SMP/E input data sets to install Zowe are provided as compressed files in AZWE001.pax.Z. This pax archive file holds the SMP/E MCS and RELFILEs.

- **AZWE001.readme.txt (text)**
  The README file AZWE001.readme.txt is a single JCL file containing a job with the job steps you need to begin the installation, including comprehensive comments on how to tailor them. There is a sample job step that executes the z/OS UNIX System Services pax command to extract package archives. This job also executes the GIMUNZIP program to expand the package archives so that the data sets can be processed by SMP/E.

  Review this file on your desktop and follow the instructions that apply to your system.

**Allocate file system to hold the download package**

You can either create a new z/OS UNIX file system (zFS) or create a new directory in an existing file system to place AZWE001.pax.Z. The directory that will contain the download package must reside on the z/OS system where the function will be installed.

To create a new file system, and directory, for the download package, you can use the following sample JCL (FILESYS).
Copy and paste the sample JCL into a separate data set, uncomment the job, and modify the job to update required parameters before submitting it.

```plaintext
//FILESYS  JOB <job parameters>
//***************************************************************
//* This job must be updated to reflect your environment.
//* This sample:
//*  . Allocates a new z/OS UNIX file system
//*  . Creates a mount point directory
//*  . Mounts the file system
//*  - Provide valid job card information
//*  - Change:
//*    @zfs_path@
//*    ----+----1----+----2----+----3----+----4----+----5
//*        - To the absolute z/OS UNIX path for the download
//*        package (starting with /)
//*        - Maximum length is 50 characters
//*        - Do not include a trailing /
//*    @zfs_dsn@
//*        - To your file system data set name
//*  - Your userid MUST be defined as a SUPERUSER to successfully
//*    run this job
//****************************************************************
//CREATE   EXEC PGM=IDCAMS,REGION=0M,COND=(0,LT)
//SYSPRINT DD SYSOUT=* 
//SYSSIN DD *
DEFINE CLUSTER ( -
    NAME(@zfs_dsn@) -

oshell umask 0022; +
mkdir -p @zfs_path@
MOUNT +
FILESYSTEM('@zfs_dsn@') +
MOUNTPOINT('@zfs_path@') +
MODE(RDWR) TYPE(ZFS) PARM('AGGRGROW')
//

Expected Return Codes and Messages: You will receive a return code of 0 if this job runs correctly.
```
Upload the download package to the host

Upload the AZWE001.readme.txt file in text format and the AZWE001.pax.Z file in binary format from your workstation to the z/OS UNIX file system. The instructions in this section are also in the AZWE001.readme.txt file that you downloaded.

There are many ways to transfer the files or make them available to the z/OS system where the package will be installed. In the following sample dialog, we use FTP from a Microsoft Windows command line to do the transfer. This assumes that the z/OS host is configured as an FTP host/server and that the workstation is an FTP client. Commands or other information entered by the user are in bold, and the following values are assumed.

<table>
<thead>
<tr>
<th>User enters:</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>mvssaddr</td>
<td>TCP/IP address or hostname of the z/OS system</td>
</tr>
<tr>
<td>tsouid</td>
<td>Your TSO user ID</td>
</tr>
<tr>
<td>tsopw</td>
<td>Your TSO password</td>
</tr>
<tr>
<td>d:</td>
<td>Location of the downloaded files</td>
</tr>
<tr>
<td>@zfs_path@</td>
<td>z/OS UNIX path where to store the files. This matches the @zfs_path@ variable you specified in the previous step.</td>
</tr>
</tbody>
</table>

Important! The AZWE001.pax.Z file must be uploaded to the z/OS driving system in binary format, or the subsequent UNPAX step will fail.

Sample FTP upload scenario:

```
C:/ftp mvssaddr
Connected to mvssaddr.200-FTPD1 IBM FTP CS %version% at mvssaddr, %time% on %date %. 220 Connection will close if idle for more than 5 minutes. User (mvssaddr:(none)): tsouid
331 Send password please. tsopw
230 tsouid is loaded on. Working directory is "tsouid.".
ftp> cd @zfs_path@
250 HFS directory @zfs_path@ is the current working directory.
ftp> ascii
200 Representation type is Ascii NonPrint
ftp> put c:/AZWE001.readme.txt
200 Port request OK. 150 Storing data set @zfs_path@/AZWE001.readme.txt 250 Transfer completed successfully.
ftp: 0344 bytes sent in 0.01 sec. (1366.67 Kbs)
```

If you are unable to connect with ftp and only able to use sftp, the commands above are the same except that you will use sftp at the command prompt instead of ftp. Also, because sftp only supports binary file transfer, the ascii and binary commands should be omitted. After you transfer the AZWE001.readme.txt file, it will be in an ASCII codepage so you need to convert it to EBCDIC before it can be used. To convert AZWE001.readme.txt to EBCDIC, log in to the distribution system using ssh and run anICONV command.

```
C:/ssh tsouid@mvssaddr
tsouid@mvssaddr's password: tsopw/a/
tsouid: cd:@zfs_path@:@zfs_path:@xicon -f ISO8859-1 -t IBM-1047 AZWE001.readme.txt > AZWE001.readme.EBCDIC:@zfs_path:@rm AZWE001.readme.txt:@zfs_path:@mv AZWE001.readme.EBCDIC AZWE001.readme.txt:@zfs_path:@exitC:
```

Extract and expand the compressed SMPMCS and RELFILEs

The AZWE001.readme.txt file uploaded in the previous step holds a sample JCL to expand the compressed SMPMCS and RELFILEs from the uploaded AZWE001.pax.Z file into data sets for use by the SMP/E RECEIVE job. The JCL is repeated here for your convenience.

- @zfs_path@ matches the variable that you specified in the previous step.
- If the osshell command gets a RC=256 and message "pax: checksum error on tape (got ee2e, expected 0)", then the archive file was not uploaded to the host in binary format.
• GIMUNZIP allocates data sets to match the definitions of the original data sets. You might encounter errors if your SMS ACS routines alter the attributes used by GIMUNZIP. If this occurs, specify a non-SMS managed volume for the GIMUNZIP allocation of the data sets. For example:

```plaintext
storclas="storage_class" volume="data_set_volume"
newname="...">
```

• Normally, your Automatic Class Selection (ACS) routines decide which volumes to use. Depending on your ACS configuration, and whether your system has constraints on disk space, units, or volumes, some supplied SMP/E jobs might fail due to volume allocation errors. See GIMUNZIP on page 89 for more details.

```plaintext
//EXTRACT  JOB <job parameters>
//" - Change:
//  
//" @PREFIX@
//  
//" 1-2-3-4-5
//  
//" - To your desired data set name prefix
//  
//" 25 characters
//  
//" - This value is used for the names of the
data sets extracted from the download-package
//  
//" @zfs_path@
//  
//" 3-4-5
//  
//" - To the absolute z/OS UNIX path for the download
//  
//" package (starting with /)
//  
//" 50 characters
//  
//" - Do not include a trailing /
//  
//" UNPAX    EXEC PGM=IKJEFT01,REGION=0M,COND=(0,LT)
//  SYSXEXEC DD DISP=SHR,DSN=SYS1.SBPXEXEC
//  SYSTSPRT DD SYSOUT=*  
//  SYSTSN   DD *  
//          oshell cd @zfs_path@/ ;  
//          pax -rvf AZWE001.pax.Z
//  
//" GIMUNZIP EXEC PGM=GIMUNZIP,REGION=0M,COND=(0,LT)
//  STEPLIB  DD DISP=SHR,DSN=SYS1.MIGLIB
//  SYST3    DD UNIT=SYSALLDA,SPACE=(CYL,(50,10))
//  SYST4    DD UNIT=SYSALLDA,SPACE=(CYL,(25,5))
//  SMPOUT   DD SYSOUT=" 
//  SYSPRINT DD SYSOUT=" 
//  SMPDIR   DD PATHDISP=KEEP,  
//  PATH='@zfs_path@/'
//  SYSD    DD *
//  <GIMUNZIP>
//ARCHDEF archid="AZWE001.SMPMCS"
//newname="@PREFIX@.ZOWE.AZWE001.SMPMCS"/>
//ARCHDEF archid="AZWE001.F1"
//newname="@PREFIX@.ZOWE.AZWE001.F1"/>
//ARCHDEF archid="AZWE001.F2"
//newname="@PREFIX@.ZOWE.AZWE001.F2"/>
//ARCHDEV archid="AZWE001.F3"
```
GIMUNZIP

The GIMUNZIP job may issue allocation error messages for SYSUT1 similar to these:

```
IEF244I ZWE0GUNZ GIMUNZIP - UNABLE TO ALLOCATE 1 UNIT(S)  577
   AT LEAST 1 OFFLINE UNIT(S) NEEDED.
IEF877E ZWE0GUNZ NEEDS 1 UNIT(S)  578
FOR GIMUNZIP SYSUT1
FOR VOLUME SCRTCH-  1
OFFLINE
0AA4-0AA6 0AD0-0AD4 :
*07 IEF238D ZWE0GUNZ - REPLY DEVICE NAME OR 'CANCEL'.
CNZ2605I At 10.10.22 the system will automatically  581
reply: CANCEL
to the following WTOR:
0007 IEF238D ZWE0GUNZ - REPLY DEVICE NAME OR 'CANCEL'.
R 0007,CANCEL
IKJ56883I FILE SYSUT1 NOT ALLOCATED, REQUEST CANCELED
- ---TIMINGS (MINS.)---
- JOBNAME   STEPNAM   PROCSTEP   RC   EXCP   TCB    SRB  CLOCK
- ZWE0GUNZ   12    2311 ******    .00    2.4
- ZWE0GUNZ ENDED. NAME- TOTAL TCB CPU TIME=
$HASP395 ZWE0GUNZ ENDED - RC=0012
```

The job will end with RC=12. If this happens, add a TEMPDS control statement to the existing SYSIN as shown below:

```
//SYSIN DD *
<GIMUNZIP>
<TEMPDS volume="&VOLSER"> </TEMPDS>
<ARCHDEF archid="&FMID..SMPMCS"
newname="@PREFIX@.ZOWE.&FMID..SMPMCS"/>
<ARCHDEF archid="&FMID..F1"
newname="@PREFIX@.ZOWE.&FMID..F1"/>
<ARCHDEF archid="&FMID..F2"
newname="@PREFIX@.ZOWE.&FMID..F2"/>
<ARCHDEF archid="&FMID..F4"
newname="@PREFIX@.ZOWE.&FMID..F4"/>
</GIMUNZIP>
//*
```

where, &VOLSER is a DISK volume with sufficient free space to hold temporary copies of the RELFILES. As a guide, this may require 1,000 cylinders, or about 650 MB.

Sample installation jobs

The following sample installation jobs are provided in hlq.ZOWE.AZWE001.F1, or equivalent, as part of the project to help you install Zowe:

<table>
<thead>
<tr>
<th>Job Name</th>
<th>Job Type</th>
<th>Description</th>
<th>RELFILE</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZWE1SMPE</td>
<td>SMP/E</td>
<td>Sample job to create an SMP/E environment (optional)</td>
<td>ZOWE.AZWE001.F1</td>
</tr>
<tr>
<td>Job Name</td>
<td>Job Type</td>
<td>Description</td>
<td>RELFILE</td>
</tr>
<tr>
<td>------------</td>
<td>-----------</td>
<td>------------------------------------------------------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>ZWE2RCVE</td>
<td>RECEIVE</td>
<td>Sample SMP/E RECEIVE job</td>
<td>ZOWE.AZWE001.F1</td>
</tr>
<tr>
<td>ZWE3ALOC</td>
<td>ALLOCATE</td>
<td>Sample job to allocate target and distribution libraries</td>
<td>ZOWE.AZWE001.F1</td>
</tr>
<tr>
<td>ZWE4ZFS</td>
<td>ALLOMZFS</td>
<td>Sample job to allocate, create mountpoint, and mount zFS data sets</td>
<td>ZOWE.AZWE001.F1</td>
</tr>
<tr>
<td>ZWE5MKD</td>
<td>MKDIR</td>
<td>Sample job to invoke the supplied ZWEMKDIR EXEC to allocate file system paths</td>
<td>ZOWE.AZWE001.F1</td>
</tr>
<tr>
<td>ZWE6DDEF</td>
<td>DDDEF</td>
<td>Sample job to define SMP/E DDDEFs</td>
<td>ZOWE.AZWE001.F1</td>
</tr>
<tr>
<td>ZWE7APLY</td>
<td>APPLY</td>
<td>Sample SMP/E ACCEPT job</td>
<td>ZOWE.AZWE001.F1</td>
</tr>
<tr>
<td>ZWE8ACPT</td>
<td>ACCEPT</td>
<td>Sample SMP/E ACCEPT job</td>
<td>ZOWE.AZWE001.F1</td>
</tr>
</tbody>
</table>

**Note:** When Zowe is downloaded from the web, the RELFILE data set name will be prefixed by your chosen high-level qualifier, as documented in the Extract and expand the compressed SMPMCS and RELFILEs on page 87 section.

You can access the sample installation jobs by performing an SMP/E RECEIVE (refer to Perform SMP/E RECEIVE), then copy the jobs from the RELFILES to a work data set for editing and submission.

You can also copy the sample installation jobs from the product files by submitting the following job. Before you submit the job, add a job statement and change the lowercase parameters to uppercase values to meet the requirements of your site.

```plaintext
//STEP1   EXEC PGM=IEBCOPY
//SYSPRINT DD SYSOUT=*,
//IN      DD DSN=ZOWE.AZWE001.F1,
//         DISP=SHR,
//         VOL=SER=filevol,
//         UNIT=SYSALLDA
//OUT     DD DSN=jcl-library-name,
//         DISP=(NEW,CATLG,DELETE),
//         SPACE=(TRK,(5,5,5)),
//         VOL=SER=dasdvol,
//         UNIT=SYSALLDA
//SYSUT3  DD UNIT=SYSALLDA,SPACE=(CYL,(1,1))
//SYSIN   DD *
//COPY INDD=IN,OUTDD=OUT
/*
```

See the following information to update the statements in the sample above:

- **IN:**
  - **filevol** is the volume serial of the DASD device where the downloaded files reside.
• OUT:
  • jcl-library-name is the name of the output data set where the sample jobs are stored.
  • dasdvol is the volume serial of the DASD device where the output data set resides. Uncomment the statement if a volume serial must be provided.

The following supplied jobs might fail due to disk space allocation errors, as mentioned above for GIMUNZIP on page 89. Review the following sections for example error and actions that you can take to resolve the error.

- **ZWE2RCVE** on page 91
- **ZWE1SMPE and ZWE4ZFS** on page 91
- **ZWEMKDIR, ZWE1SMPE, ZWE2RCVE, ZWE3ALOC, ZWE4ZFS and ZWE5MKD**

**ZWE2RCVE**

```
IEC032I E37-04,IGC0005E,ZWE2RCVE,RECEIVE,SMPLIB,0AC0,USER10,
ZOWE.SMPE.AZWE001.F4
```

Add space and directory allocations to this SMPCNTL statement in the preceding ZWE1SMPE job:

```
ADD DDDEF(SMPLIB)  UNIT(SYSALLDA)  .
```

This makes it as below:

```
ADD DDDEF(SMPLIB) CYL SPACE(2,1) DIR(10)  UNIT(SYSALLDA)  .
```

**ZWE1SMPE and ZWE4ZFS**

Example error

```
IDC3506I REQUIRED VOLUMES AND/OR DEVICETYPES HAVE BEEN OMITTED
IDC3003I FUNCTION TERMINATED. CONDITION CODE IS 12
IDC0002I IDCAMS PROCESSING COMPLETE. MAXIMUM CONDITION CODE WAS 12
```

Uncomment the VOLUMES(...) control statements and refer to the comments at the start of the JCL job for related necessary changes.

**ZWEMKDIR, ZWE1SMPE, ZWE2RCVE, ZWE3ALOC, ZWE4ZFS and ZWE5MKD**

Example error

```
IEF257I ZWE3ALOC ALLOCD ALLOCD AZWEZFS - SPACE REQUESTED NOT AVAILABLE
IEF272I ZWE3ALOC ALLOCD ALLOCD - STEP WAS NOT EXECUTED.
```

Uncomment the VOL=SER=&... control statements and refer to the comments at the start of the JCL job for related necessary changes.

**Create SMP/E environment (Optional)**

If you choose to create a new SMP/E environment for this install, you can use one of the following two options.

- Create the SMP/E environment using JCL
- Create the SMP/E environment with z/OSMF workflow

**Create SMP/E Environment using JCL**

A sample job ZWE1SMPE is provided or you may choose to use your own JCL. If you are using an existing CSI, do not run the sample job ZWE1SMPE. If you choose to use the sample job provided, edit and submit ZWE1SMPE. Consult the instructions in the sample job for more information.

**Note:** If you want to use the default of letting your Automatic Class Selection (ACS) routines decide which volume to use, comment out the following line in the sample job ZWE1SMPE.
// SET CSIVOL=#csivol

Expected Return Codes and Messages: You will receive a return code of 0 if this job runs correctly.

Create SMP/E Environment with z/OSMF Workflow

z/OSMF workflow simplifies the procedure to create an SMP/E environment for Zowe. Register and execute the Zowe SMP/E workflow to create SMP/E environment in the z/OSMF web interface. Perform the following steps to register and execute the Zowe workflow in the z/OSMF web interface:

1. Log in to the z/OSMF web interface.
2. Select Workflows from the navigation tree.
3. Select Create Workflow from the Actions menu.
4. Enter the complete path to the workflow definition file in the Workflow Definition field.

   The workflow is located in the ZWEWRF01 member of the hlq.ZOWE.AZWE001.F4 data set.
5. (Optional) Enter the path to the customized variable input file that you prepared in advance.

   The variable input file is located in ZWEYML01 member of the hlq.ZOWE.AZWE001 data set.

   Create a copy of the variable input file. Modify the file as necessary according to the built-in comments. Set the field to the path where the new file is located. When you execute the workflow, the values from the variable input file override the workflow variables default values.
6. Select the system where you want to execute the workflow.
7. Select Next.
8. Specify the unique workflow name.
9. Select or enter an Owner Use ID and select Assign all steps to owner user ID.
10. Select Finish.

   The workflow is registered in z/OSMF and ready to execute.
11. Select the workflow that you registered from the workflow list.
12. Execute the steps in order.

   For general information about how to execute z/OSMF workflow steps, watch the z/OSMF Workflows Tutorial.
13. Perform the following steps to execute each step individually:

   a. Double-click the title of the step.
   b. Select the Perform tab.
   c. Review the step contents and update the input values as required.
   d. Select Next.
   e. Repeat the previous two steps to complete all items until the option Finish is available.
   f. Select Finish.

   After you execute each step, the step is marked as Complete. The workflow is executed.

After you complete executing all the steps individually, the Zowe SMP/E is created.

Perform SMP/E RECEIVE

Edit and submit sample job ZWE2RCVE to perform the SMP/E RECEIVE for Zowe. Consult the instructions in the sample job for more information.

Expected Return Codes and Messages: You will receive a return code of 0 if this job runs correctly.

Allocate SMP/E target and distributions libraries

Edit and submit sample job ZWE3ALOC to allocate the SMP/E target and distribution libraries for Zowe. Consult the instructions in the sample job for more information.

Expected Return Codes and Messages: You will receive a return code of 0 if this job runs correctly.

Allocate, create and mount ZSF files (Optional)

This job allocates, creates a mountpoint, and mounts zFS data sets.
If you plan to install Zowe into a new z/OS UNIX file system, you can edit and submit the optional ZWE4ZFS job to perform the following tasks. Consult the instructions in the sample job for more information.

- Create the z/OS UNIX file system
- Create a mountpoint
- Mount the z/OS UNIX file system on the mountpoint

The recommended z/OS UNIX file system type is zFS. The recommended mountpoint is /usr/lpp/zowe.

Before running the sample job to create the z/OS UNIX file system, you must ensure that OMVS is active on the driving system. zFS must be active on the driving system if you are installing Zowe into a file system that is zFS.

If you create a new file system for this product, consider updating the BPXPRMxx PARMLIB member to mount the new file system at IPL time. This action can be helpful if an IPL occurs before the installation is completed.

```
MOUNT FILESYSTEM('#dsn')
MOUNTPOINT('/usr/lpp/zowe')
MODE(RDWR)        /* can be MODE(READ) */
TYPE(ZFS) PARM('AGGRGROW') /* zFS, with extents */
```

See the following information to update the statements in the previous sample:

- `#dsn` is the name of the data set holding the z/OS UNIX file system.
- `/usr/lpp/zowe` is the name of the mountpoint where the z/OS UNIX file system will be mounted.

**Expected Return Codes and Messages:** You will receive a return code of 0 if this job runs correctly.

**Allocate z/OS UNIX paths**

The target system HFS or zFS data set must be mounted on the driving system when running the sample ZWE5MKD job since the job will create paths in the HFS or zFS.

Before running the sample job to create the paths in the file system, you must ensure that OMVS is active on the driving system and that the target system's HFS or zFS file system is mounted on the driving system. zFS must be active on the driving system if you are installing Zowe into a file system that is zFS.

If you plan to install Zowe into a new HFS or zFS file system, you must create the mountpoint and mount the new file system on the driving system for Zowe.

The recommended mountpoint is /usr/lpp/zowe.

Edit and submit sample job ZWE5MKD to allocate the HFS or zFS paths for Zowe. Consult the instructions in the sample job for more information.

If you create a new file system for this product, consider updating the BPXPRMxx PARMLIB member to mount the new file system at IPL time. This action can be helpful if an IPL occurs before the installation is completed.

**Expected Return Codes and Messages:** You will receive a return code of 0 if this job runs correctly.

**Create DDDEF entries**

Edit and submit sample job ZWE6DDEF to create DDDEF entries for the SMP/E target and distribution libraries for Zowe. Consult the instructions in the sample job for more information.

If you create a new file system for this product, consider updating the BPXPRMxx PARMLIB member to mount the new file system at IPL time. This action can be helpful if an IPL occurs before the installation is completed.

**Expected Return Codes and Messages:** You will receive a return code of 0 if this job runs correctly.

**Perform SMP/E APPLY**

In this step, you run the sample job ZWE7APLY to apply Zowe. This step can take a long time to run, depending on the capacity of your system, and on what other jobs are running.

**Follow these steps**
1. Ensure that you have the latest HOLDDATA; then edit and submit sample job ZWE7APLY to perform an SMP/E APPLY CHECK for Zowe. Consult the instructions in the sample job for more information.

The latest HOLDDATA is available through several different portals, including http://service.software.ibm.com/holdata/390holddata.html. The latest HOLDDATA may identify HIPER and FIXCAT APARs for the FMIDs you will be installing. An APPLY CHECK will help you determine whether any HIPER or FIXCAT APARs are applicable to the FMIDs you are installing. If there are any applicable HIPER of FIXCAT APARs, the APPLY CHECK will also identify fixing PTFs that will resolve the APARs, if a fixing PTF is available.

You should install the FMIDs regardless of the status of unresolved HIPER or FIXCAT APARs. However, do not deploy the software until the unresolved HIPER and FIXCAT APARs have been analyzed to determine their applicability. That is, before deploying the software either ensure fixing PTFs are applied to resolve all HIPER or FIXCAT APARs, or ensure the problems reported by all HIPER or FIXCAT APARs are not applicable to your environment.

To receive the full benefit of the SMP/E Causer SYSMOD Summary Report, do not bypass the PRE, ID, REQ, and IFREQ on the APPLY CHECK. The SMP/E root cause analysis identifies the cause only of errors and not of warnings (SMP/E treats bypassed PRE, ID, REQ, and IFREQ conditions as warnings, instead of errors).

Here are sample APPLY commands:

a. To ensure that all recommended and critical service is installed with the FMIDs, receive the latest HOLDDATA and use the APPLY CHECK command as follows

```plaintext
APPLY S(fmid,fmid,...) CHECK
FORFMID(fmid,fmid,...)
SOURCEID(RSU*)
FIXCAT(IBM.PRODUCTINSTALL-REQUIREDSERVICE)
GROUPEXTEND.
```

• Some HIPER APARs might not have fixing PTFs available yet. You should analyze the symptom flags for the unresolved HIPER APARs to determine if the reported problem is applicable to your environment and if you should bypass the specific ERROR HOLDs in order to continue the installation of the FMIDs.

• This method requires more initial research, but can provide resolution for all HIPERs that have fixing PTFs available and not in a PE chain. Unresolved PEs or HIPERs might still exist and require the use of BYPASS.

a. To install the FMIDs without regard for unresolved HIPER APARs, you can add the BYPASS(HOLDCLASS(HIPER)) operand to the APPLY CHECK command. This will allow you to install FMIDs, even though one or more unresolved HIPER APARs exist. After the FMIDs are installed, use the SMP/E REPORT ERRSYSMODS command to identify unresolved HIPER APARs and any fixing PTFs.

```plaintext
APPLY S(fmid,fmid,...) CHECK
FORFMID(fmid,fmid,...)
SOURCEID(RSU*)
FIXCAT(IBM.PRODUCTINSTALL-REQUIREDSERVICE)
GROUPEXTEND
BYPASS(HOLDCLASS(HIPER)).
```

• This method is quicker, but requires subsequent review of the Exception SYSMOD report produced by the REPORT ERRSYSMODS command to investigate any unresolved HIPERs. If you have received the latest HOLDDATA, you can also choose to use the REPORT MISSINGFIX command and specify Fix Category IBM.PRODUCTINSTALL-REQUIREDSERVICE to investigate missing recommended service.

• If you bypass HOLDs during the installation of the FMIDs because fixing PTFs are not yet available, you can be notified when the fixing PTFs are available by using the APAR Status Tracking (AST) function of the ServiceLink or the APAR Tracking function of Resource Link.

2. After you take actions that are indicated by the APPLY CHECK, remove the CHECK operand and run the job again to perform the APPLY.

Note: The GROUPEXTENDED operand indicates the SMP/E applies all requisite SYSMODs. The requisite SYSMODs might be applicable to other functions.
Expected Return Codes and Messages from APPLY CHECK: You will receive a return code of 0 if the job runs correctly.

Expected Return Codes and Messages from APPLY: You will receive a return code of 0 if the job runs correctly.

Perform SMP/E ACCEPT

Edit and submit sample job ZWE8ACPT to perform an SMP/E ACCEPT CHECK for Zowe. Consult the instructions in the sample job for more information.

To receive the full benefit of the SMP/E Causer SYSMOD Summary Report, do not bypass the PRE, ID, REQ, and IFREQ on the ACCEPT CHECK. The SMP/E root cause analysis identifies the cause of errors but not warnings (SMP/E treats bypassed PRE, ID, REQ, and IFREQ conditions as warnings rather than errors).

Before you use SMP/E to load new distribution libraries, it is recommended that you set the ACCICLIN indicator in the distribution zone. In this way, you can save the entries that are produced from JCLIN in the distribution zone whenever a SYSMOD that contains inline JCLIN is accepted. For more information about the ACCICLIN indicator, see the description of inline JCLIN in the SMP/E Commands book for details.

After you take actions that are indicated by the ACCEPT CHECK, remove the CHECK operand and run the job again to perform the ACCEPT.

Note: The GROUPEXTEND operand indicates that SMP/E accepts all requisite SYSMODs. The requisite SYSMODS might be applicable to other functions.

Expected Return Codes and Messages from ACCEPT CHECK: You will receive a return code of 0 if this job runs correctly.

If PTFs that contain replacement modules are accepted, SMP/E ACCEPT processing will link-edit or bind the modules into the distribution libraries. During this processing, the Linkage Editor or Binder might issue messages that indicate unresolved external references, which will result in a return code of 4 during the ACCEPT phase. You can ignore these messages, because the distribution libraries are not executable and the unresolved external references do not affect the executable system libraries.

Expected Return Codes and Messages from ACCEPT: You will receive a return code of 0 if this job runs correctly.

Run REPORT CROSSZONE

The SMP/E REPORT CROSSZONE command identifies requisites for products that are installed in separate zones. This command also creates APPLY and ACCEPT commands in the SMPPUNCH data set. You can use the APPLY and ACCEPT commands to install those cross-zone requisites that the SMP/E REPORT CROSSZONE command identifies.

After you install Zowe, it is recommended that you run REPORT CROSSZONE against the new or updated target and distribution zones. REPORT CROSSZONE requires a global zone with ZONEINDEX entries that describe all the target and distribution libraries to be reported on.

For more information about REPORT CROSSZONE, see the SMP/E manuals.

Cleaning up obsolete data sets, paths, and DDDEFs

The web download data sets listed in DASD storage requirements on page 82 are temporary data sets. You can delete these data sets after you complete the SMP/E installation.

Activating Zowe

File system execution

If you mount the file system in which you have installed Zowe in read-only mode during execution, then you do not have to take further actions to activate Zowe.

Zowe customization

You can find the necessary information about customizing and using Zowe on the Zowe doc site.
• For more information about how to customize Zowe, see Zowe Application Framework configuration on page 120.
• For more information about how to use Zowe, see Getting started tutorial on page 142.

Configuring the z/OS system for Zowe

Configure the z/OS security manager to prepare for launching the Zowe started tasks.

If Zowe has already been launched on a z/OS system from a previous release of Version 1.8 or later, then you are applying a newer Zowe build. You can skip this security configuration step unless told otherwise in the release documentation.

A SAMPLIB JCL member ZWESECUR is provided to assist with the security configuration. You can submit the ZWESECUR JCL member as-is or customize it depending on site preferences. The JCL allows you to vary which security manager you use by setting the PRODUCT variable to be one of RACF, ACF2, or TSS.

```
// SET PRODUCT=RACF * RACF, ACF2, or TSS
```

If ZWESECUR encounters an error or a step that has already been performed, it will continue to the end, so it can be run repeatedly in a scenario such as a pipeline automating the configuration of a z/OS environment for Zowe installation.

It is expected that the security administrator at a site will want to review, edit where necessary, and either execute ZWESECUR as a single job or else execute individual TSO commands one by one to complete the security configuration of a z/OS system in preparation for installing and running Zowe.

**Note:** You are required to manually perform an additional step for the Top Secret (TSS) external security product. This step is not a part of the ZWESECUR job. For more information, see Configure multi-user address space (for TSS only).

If you want to undo all of the z/OS security configuration steps performed by the JCL member ZWESECUR, Zowe provides a reverse member ZWENOSEC that contains the inverse steps that ZWESECUR performs. This is useful in the following situations:

• You are configuring z/OS systems as part of a build pipeline that you want to undo and redo configuration and installation of Zowe using automation.
• You have configured a z/OS system for Zowe that you no longer want to use and you prefer to delete the Zowe user IDs and undo the security configuration settings rather than leave them enabled.

If you run ZWENOSEC on a z/OS system, then you will no longer be able to run Zowe until you rerun ZWESECUR to reinitialize the z/OS security configuration.

User IDs and groups for the Zowe started tasks

Zowe requires a user ID ZWESVUSR to execute its main z/OS runtime started task ZWESVSTC. This userid must have a valid OMVS segment.

Zowe requires a user ID ZWESIUSR to execute the cross memory server started task ZWESISTC. This userid must have a valid OMVS segment.

Zowe requires a group ZWEADMIN that both ZWESVUSR and ZWESIUSR should belong to. This group must have a valid OMVS segment.

The JCL member ZWESECUR contains the TSO commands to create the user IDs.

• To create the ZWEADMIN group, issue the following command:

```
ADDGROUP ZWEADMIN OMVS(AUTOGID) -
DATA('STARTED TASK GROUP WITH OMVS SEGMEMENT')
```

• To create the ZWESVUSR user ID for the main Zowe started task, issue the following command:

```
ADDUSER ZWESVUSR -
```
**User Guide**

**Configure ZWESVSTC to run under ZWESVUSR user ID**

When the Zowe started task ZWESVSTC is started, it must be associated with the user ID ZWESVUSR and group ZWEADMIN. A different user ID and group can be used if required to conform with existing naming standards.

- If you use RACF, issue the following commands:

```
RDEFINE STARTED ZWESVSTC.* UACC(NONE) STDATA(USER(ZWESVUSR) GROUP(ZWEADMIN) PRIVILEGED(NO) TRUSTED(NO) TRACE(YES))
SETROPTS REFRESH RACLIST(STARTED)
```

- If you use CA ACF2, issue the following commands:

```
SET CONTROL(GSO)
INSERT STC,ZWESVSTC LOGONID(ZWESVUSR) GROUP(ZWEADMIN) STCID(ZWESVSTC) F ACF2,REFRESH(STC)
```

- If you use CA Top Secret, issue the following commands:

```
TSS ADDTO(STC) PROCNAME(ZWESVSTC) ACID(ZWESVUSR)
```

**Grant users permission to access z/OSMF**

TSO user IDs using Zowe must have permission to access the z/OSMF services that are used by Zowe. They should be added to the group with appropriate z/OSMF privileges, IZUUSER or IZUADMIN by default.

- If you use RACF, issue the following command:

```
CONNECT (userid) GROUP(IZUUSER)
```

- If you use CA ACF2, issue the following commands:

```
ACFNRULE TYPE(TGR) KEY(IZUUSER) ADD(UID(<uid string of user>) ALLOW)
F ACF2,REBUILD(TGR)
```

- If you use CA Top Secret, issue the following commands:

```
TSS ADD(userid) PROFILE(IZUUSER)
TSS ADD(userid) GROUP(IZUUSRGP)
```

**Configure the cross memory server for SAF**

Zowe has a cross memory server that runs as an APF-authorized program with key 4 storage. Client processes accessing the cross memory server's services must have READ access to a security profile ZWES.IS in the FACILITY class. This authorization step is used to guard against access by non-privileged clients.

Activate the FACILITY class, define a ZWES.IS profile, and grant READ access to the user ID ZWESVUSR. This is the user ID that the Zowe started task ZWESVSTC runs under.
To do this, issue the following commands that are also included in the ZWESECUR JCL member. The commands assume that you run the ZWESVSTC under the ZWESVUSR user.

- If you use RACF, issue the following commands:
  - To see the current class settings, use:
    ```
    SETROPTS LIST
    ```
  - To define and activate the FACILITY class, use:
    ```
    SETROPTS GENERIC(FACILITY)
    SETROPTS CLASSACT(FACILITY)
    ```
  - To RACLIST the FACILITY class, use:
    ```
    SETROPTS RACLIST(FACILITY)
    ```
  - To RACLIST the FACILITY class, use:
    ```
    SETROPTS RACLIST(FACILITY) REFRESH
    ```
  - To check whether the permission has been successfully granted, issue the following command:
    ```
    RLIST FACILITY ZWES.IS AUTHUSER
    ```
    This shows the user IDs who have access to the ZWES.IS class, which should include Zowe's started task userid with READ access.
  - If you use CA ACF2, issue the following commands:
    ```
    SET RESOURCE(FAC)
    RECKEY ZWES ADD(IS ROLE(IZUSVR) SERVICE(READ) ALLOW)
    F ACF2,REBUILD(FAC)
    ```
  - If you use CA Top Secret, issue the following commands, where owner-acid can be IZUSVR or a different ACID:
    ```
    TSS ADD(`owner-acid`) IBMFAC(ZWES.)
    TSS PERMIT(ZWESVUSR) IBMFAC(ZWES.IS) ACCESS(READ)
    ```

**Notes:**

- The cross memory server treats "no decision" style SAF return codes as failures. If there is no covering profile for the ZWES.IS resource in the FACILITY class, the request will be denied.
- Cross memory server clients other than Zowe might have additional SAF security requirements. For more information, see the documentation for the specific client.
Configure security environment switching

Typically, the user ZWESVUSR that the ZWESVSTC started task runs under needs to be able to change the security environment of its process to allow API requests to be issued on behalf of the logged on TSO user ID, rather than the server's user ID. This capability provides the functionality that allows users to log on to the Zowe desktop and use apps such as the File Editor to list data sets or USS files that the logged on user is authorized to view and edit, rather than the user ID running the Zowe server. This technique is known as impersonation.

To enable impersonation, you must grant the user ID ZWESVUSR associated with the ZWESVSTC started task UPDATE access to the BPX.SERVER and BPX.DAEMON profiles in the FACILITY class.

You can issue the following commands first to check whether you already have the impersonation profiles defined as part of another server configuration, such as the FTPD daemon. Review the output to confirm that the two impersonation profiles exist and the user ZWESVUSR who runs the ZWESVSTC started task has UPDATE access to both profiles.

- If you use RACF, issue the following commands:
  
  ```
  RLIST FACILITY BPX.SERVER AUTHUSER
  RLIST FACILITY BPX.DAEMON AUTHUSER
  ```

- If you use CA Top Secret, issue the following commands:

  ```
  TSS WHOHAS IBMFAC(BPX.SERVER)
  TSS WHOHAS IBMFAC(BPX.DAEMON)
  ```

- If you use CA ACF2, issue the following commands:

  ```
  SET RESOURCE(FAC)
  LIST BPX
  ```

If the user ZWESVUSR who runs the ZWESVSTC started task does not have UPDATE access to both profiles follow the instructions below.

- If you use RACF, complete the following steps:

  1. Activate and RACLIST the FACILITY class. This may have already been done on the z/OS environment if another z/OS server has been previously configured to take advantage of the ability to change its security environment, such as the FTPD daemon that is included with z/OS Communications Server TCP/IP services.

  ```
  SETROPTS GENERIC(FACILITY)
  ```
SETROPTS CLASSACT(FACILITY) RACLIST(FACILITY)

2. Define the impersonation profiles. This may have already been done on behalf of another server such as the FTPD daemon.

   RDEFINE FACILITY BPX.SERVER UACC(NONE)

   RDEFINE FACILITY BPX.DAEMON UACC(NONE)

3. Having activated and RACLIST the FACILITY class, the user ID ZWESVUSR who runs the ZWESVSTC started task must be given update access to the BPX.SERVER and BPX.DAEMON profiles in the FACILITY class.

   PERMIT BPX.SERVER CLASS(FACILITY) ID(<zwesvstc_user>) ACCESS(UPDATE)

   PERMIT BPX.DAEMON CLASS(FACILITY) ID(<zwesvstc_user>) ACCESS(UPDATE)

   where <zwesvstc_user> is ZWESVUSR unless a different user ID is being used for the z/OS environment.

   /* Activate these changes */

   SETROPTS RACLIST(FACILITY) REFRESH

4. Issue the following commands to check whether permission has been successfully granted:

   RLIST FACILITY BPX.SERVER AUTHUSER

   RLIST FACILITY BPX.DAEMON AUTHUSER

   • If you use CA Top Secret, complete the following steps:

   1. Define the BPX Resource and access for <zwesvstc_user>.

      TSS ADD(`owner-acid`) IBMFAC(BPX.)

      TSS PERMIT(<zwesvstc_user>) IBMFAC(BPX.SERVER) ACCESS(UPDATE)

      TSS PERMIT(<zwesvstc_user>) IBMFAC(BPX.DAEMON) ACCESS(UPDATE)

      where <zwesvstc_user> is ZWESVUSR unless a different user ID is being used for the z/OS environment.

   2. Issue the following commands and review the output to check whether permission has been successfully granted:

      TSS WHOHAS IBMFAC(BPX.SERVER)

      TSS WHOHAS IBMFAC(BPX.DAEMON)
• If you use CA ACF2, complete the following steps:

  1. Define the BPX Resource and access for <zwesvstc_user>.

     ```
     SET RESOURCE (FAC)
     RECKEY BPX ADD (SERVER ROLE (<zwesvstc_user>) SERVICE (UPDATE) ALLOW)
     RECKEY BPX ADD (DAEMON ROLE (<zwesvstc_user>) SERVICE (UPDATE) ALLOW)
     ```

     where <zwesvstc_user> is ZWESVUSR unless a different user ID is being used for the z/OS environment.

     ```
     F ACF2, REBUILD (FAC)
     ```

  2. Issue the following commands and review the output to check whether permission has been successfully granted:

     ```
     SET RESOURCE (FAC)
     LIST BPX
     ```

**Configure address space job naming**

The user ID ZWESVUSR that is associated with the Zowe started task ZWESVSTC must have READ permission for the BPX.JOBNAME profile in the FACILITY class. This is to allow setting of the names for the different z/OS UNIX address spaces for the Zowe runtime components. See Address space names on page 106.

To display who is authorized to the profile, issue the following command:

```
RLIST FACILITY BPX.JOBNAME AUTHUSER
```

Additionally, you need to activate facility class, permit BPX.JOBNAME, and refresh facility class:

```
SETROPTS CLASSACT (FACILITY) RACLST (FACILITY)
PERMIT BPX.JOBNAME CLASS (FACILITY) ID (ZWESVUSR) ACCESS (READ)
SETROPTS RACLST (FACILITY) REFRESH
```

For more information, see Setting up the UNIX-related FACILITY and SURROGAT class profiles in the "z/OS UNIX System Services" documentation.

##Configure multi-user address space (for TSS only)

The ZWESVSTC started task is multiuser address space, and therefore a TSS FACILITY needs to be defined and assigned to the started task. The all acids signing on to the started task will need to be authorized to the FACILITY.

The following is an example of how to create a new TSS FACILITY.

**Example:** In the TSSPARMS, add the following lines to create the new FACILITY:

```
FACILITY (USER11=NAME=ZOWE)
FACILITY (ZOWE=MODE=FAIL)
FACILITY (ZOWE=RES)
```

For more information about how to administer Facility Matrix Table, see How to Perform Facility Matrix Table Administration.

To assign the FACILITY to the started task issue the following command:

```
TSS ADD (ZWESVUSR) MASTFAC (ZOWE)
```
To authorize a user to signon to the FACILITY, issues the following command:

```
TSS ADD(user_acid) FAC(ZOWE)
```

---

**Configuring Zowe certificates**

A keystore directory is used by Zowe to hold the certificate used for encrypting communication between Zowe clients and the Zowe z/OS servers. It also holds the truststore used to hold public keys of any servers that Zowe trusts. When a Zowe is launched the instance directory configuration file `instance.env` specifies the location of the keystore directory, see Configure instance directory.

If you have already created a keystore directory from a previous release of Version 1.8 or later, then you may reuse the existing keystore directory with newer version of Zowe.

You can use the existing certificate signed by an external certificate authority (CA) for HTTPS ports in the API Mediation Layer and the Zowe Application Framework, or else you can let the Zowe configuration script to generate a self-signed certificate by the local API Mediation CA.

If you let the Zowe configuration to generate a self-signed certificate, the certificates should be imported into your browser to avoid untrusted network traffic challenges. See Import the local CA certificate to your browser. If you do not import the certificates into your browser when you access a Zowe web page, you may be challenged that the web page cannot be trusted and, depending on the browser you are using, have to add an exception to proceed to the web page. Some browser versions may not accept the Zowe certificate because it is self-signed and the signing authority is not recognized as a trusted source. Manually importing the certificate into your browser makes it a trusted source and the challenges will no longer occur.

If you have an existing server certificate that is signed by an external CA, then you use this for the Zowe certificate. This could be a CA managed by the IT department of your company which has already ensured that any certificates signed by that CA are trusted by browsers in your company because they have included their company’s CA in their company’s browsers’ truststore. This will avoid the need to manually import the local CA into each client machine’s browsers.

If you want to avoid the need to have each browser trust the CA that has signed the Zowe certificate, you can use a public certificate authority such as Symantec, Comodo, or GoDaddy to create a certificate. These certificates are trusted by all browsers and most REST API clients. However, this option involves a manual process of requesting a certificate and may incur a cost payable to the publicly trusted CA.

It's recommended that you start with the local API Mediation Layer CA for an initial evaluation.

You can use the `<ROOT_DIR>/bin/zowe-setup-certificates.sh` script in the Zowe runtime directory to configure the certificates with the set of defined environment variables. The environment variables act as parameters for the certificate configuration are held in the file `<ROOT_DIR>/bin/zowe-setup-certificates.env`.

**Generate certificate with the default values**

The script reads the default variable values that are provided in the `<ROOT_DIR>/bin/zowe-setup-certificates.env` file and generates the certificate signed by the local API Mediation CA and keystores in the `/global/zowe/keystore` location. To set up certificates with the default environment variables, ensure that you run the following script in the Zowe runtime directory:

```
<ROOT_DIR>/bin/zowe-setup-certificates.sh
```

generates the keystore in `/global/zowe/keystore`. On many z/OS installations access to this location will be restricted to privileged users so this step should be done by a system programmer with site knowledge for where the certificate should be stored in a way that the public key can be read but private key access is controlled.

**Generate certificate with the custom values**

We recommend that you review all the parameters in the `zowe-setup-certificates.env` file and customize the values for variables to meet your requirements. For example, set your preferred location to generate certificates and keystores.
Follow the procedure to customize the values for variables in the \texttt{zowe-setup-certificates.env} file:

1. Copy the \texttt{bin/zowe-setup-certificates.env} file from the read-only location to a new <your_directory>/zowe-setup-certificates.env location.
2. Customize the values for the variables based on the descriptions that are provided in the \texttt{zowe-setup-certificates.env} file.
3. Execute the following command with the customized environment file:

   \begin{verbatim}
   bin/zowe-setup-certificates.sh -p <your_directory>/zowe-setup-certificates.env [-l <log_directory>]
   \end{verbatim}

   where \texttt{<your_directory>} specifies the location of your customized environment file and \texttt{<log_directory>} is an optional parameter that overrides the default log output directory of /global/zowe/logs, if it is writable, or ~/zowe/logs.

The keystore and certificates are generated based on the customized values in the \texttt{bin/zowe-setup-certificates.env} file.

The \texttt{zowe-setup-certificates.sh} command also generates \texttt{zowe-certificates.env} file in the KEYSTORE_DIRECTORY directory. This file is used in the Zowe instance configuration step, see Keystore configuration on page 106.

The following example shows how you can configure \texttt{zowe-setup-certificates.env} file to use the existing certificates:

1. Update the value of EXTERNAL_CERTIFICATE. The value needs to point to a keystore in PKCS12 format that contains the certificate with its private key. The file needs to be transferred as a binary to the \texttt{z/OS} system.
2. Update the value of KEYSTORE_PASSWORD. The value is a password to the PKCS12 keystore specified in the EXTERNAL_CERTIFICATE variable.
3. Update the value of EXTERNAL_CERTIFICATE_ALIAS to the alias of the server certificate in the keystore.

   \textbf{Note:} If you do not know the certificate alias, run the following command where \texttt{externalCertificate.p12} is a value of EXTERNAL_CERTIFICATE in the \texttt{zowe-setup-certificates.env} file.

   \begin{verbatim}
   keytool -list -keystore externalCertificate.p12 -storepass password -storetype pkcs12 -v
   \end{verbatim}

   Expected output:

   \begin{verbatim}
   Keystore type: PKCS12
   Keystore provider: SUN
   Your keystore contains 1 entry
   Alias name: apiml
   Creation date: Oct 9, 2019
   Entry type: PrivateKeyEntry
   Certificate chain length: 3
   ...
   \end{verbatim}

   In this case, the alias can be found in \texttt{Alias name: apiml}. Therefore, set EXTERNAL_CERTIFICATE_ALIAS=apiml.

4. Update the value of EXTERNAL_CERTIFICATE_AUTHORITIES to the path of the public certificate of the certificate authority that has signed the certificate. You can add additional certificate authorities separated by spaces (specify the complete value \textbf{in quotes}). This can be used for certificate authorities that have signed the certificates of the services that you want to access via the API Mediation Layer.

5. (Optional) If you have trouble getting the certificates and you want only to evaluate Zowe, you can switch off the certificate validation by setting \texttt{VERIFY_CERTIFICATES=false}. The HTTPS will still be used but the API Mediation Layer will not validate any certificate.

   \textbf{Important!} Switching off certificate evaluation is a non-secure setup.
Following is the part of `zowe-setup-certificates.env` file snippet that uses existing certificates:

```bash
# Should APIML verify certificates of services - true/false
VERIFY_CERTIFICATES=true
# optional - Path to a PKCS12 keystore with a server certificate for APIML
EXTERNAL_CERTIFICATE=/path/to/keystore.p12
# optional - Alias of the certificate in the keystore
EXTERNAL_CERTIFICATE_ALIAS=servercert
# optional - Public certificates of trusted CAs
EXTERNAL_CERTIFICATE_AUTHORITIES="/path/to/cacert_1.cer /path/to/cacert_2.cer"
# Select a password that is used to secure EXTERNAL_CERTIFICATE keystore
# and that will be also used to secure newly generated keystores for API
# Mediation
KEYSTORE_PASSWORD=mypass
```

You may encounter the following message:

```
apiml_cm.sh --action trust-zosmf has failed. See $LOG_FILE for more details
ERROR: z/OSMF is not trusted by the API Mediation Layer. Make sure
ZOWE_ZOSMF_HOST and ZOWE_ZOSMF_PORT variables define the desired z/OSMF
instance.
ZOWE_ZOSMF_HOST=${ZOWE_ZOSMF_HOST} ZOWE_ZOSMF_PORT=${ZOWE_ZOSMF_PORT}
You can also specify z/OSMF certificate explicitly in the ZOSMF_CERTIFICATE
environmental variable in the zowe-setup-certificates.env file.
```

This error has to be resolved before you can proceed with the next installation step.

**Notes:**

- On many z/OS systems, the certificate for z/OSMF is not signed by a trusted CA and is a self-signed certificate by the z/OS system programmer who configured z/OSMF. If that is the case, then Zowe itself will not trust the z/OSMF certificate and any function dependent on z/OSMF will not operate correctly. To ensure that Zowe trusts a z/OSMF self-signed certificate, you must use the value `VERIFY_CERTIFICATES=false` in the `zowe-setup-certificates.env` file. This is also required if the certificate is from a recognized CA but for a different host name, which can occur when a trusted certificate is copied from one source and reused within a z/OS installation for different servers other than that it was originally created for.

### Creating and configuring the Zowe instance directory

The Zowe instance directory or `<INSTANCE DIRECTORY>` contains configuration data required to launch a Zowe runtime. This includes port numbers, location of dependent runtimes such as Java, Node, z/OSMF, as well as log files. When Zowe is started, configuration data will be read from files in the instance directory and logs will be written to files in the instance directory.

The instance directory `~<INSTANCE_DIRECTORY>/bin` contains a number of key scripts

- `zowe-start.sh` is used to start the Zowe runtime by launching the ZWESVSTC started task.
- `zowe-stop.sh` is used to stop the Zowe runtime by terminating the ZWESVSTC started task.
- `zowe-support.sh` can be used to capture diagnostics around the Zowe runtime for troubleshooting and offline problem determination, see Capturing diagnostics to assist problem determination on page 289

### Prerequisites

Before creating an instance directory, ensure that you have created a keystore directory that contains the Zowe certificate. For more information about how to create a keystore directory, see Configuring Zowe certificates on page 102. Also, ensure that you have already configured the z/OS environment. For information about how to configure the z/OS environment, see Configuring the z/OS system for Zowe on page 96.
Creating an instance directory

To create an instance directory, navigate to the Zowe runtime directory \(<ZOWE_ROOT_DIR>\) and execute the following commands:

```
<ROOT_DIR>/bin/zowe-configure-instance.sh -c <PATH_TO_INSTANCE_DIR>
```

Multiple instance directories can be created and used to launch independent Zowe runtimes from the same Zowe runtime directory.

The Zowe instance directory contains a file \(\text{instance.env}\) that stores configuration data. The data is read each time Zowe is started.

The purpose of the instance directory is to hold information in the z/OS File System (zFS) that is created (such as log files) or modified (such as preferences) or configured (such as port numbers) away from the zFS runtime directory for Zowe. This allows the runtime directory to be read only and to be replaced when a new Zowe release is installed, with customizations being preserved in the instance directory.

If you have an instance directory that is created from a previous release of Zowe 1.8 or later and are installing a newer release of Zowe, then you should run `zowe-configure-instance.sh -c <PATH_TO_INSTANCE_DIR>` pointing to the existing instance directory to have it updated with any new values. The release documentation for each new release will specify when this is required, and the file `manifest.json` within each instance directory contains information for which Zowe release it was created from.

In order to allow the `ZWESVSTC` started task to have permission to access the contents of the \(<\text{INSTANCE_DIR}>\) the `zowe-configure-instance.sh` script sets the group ownership of the top level directory and its child to `ZWEADMIN`. If a different group is used for the `ZWESVSTC` started task you can specify this with the optional `-g` argument, for example.

```
<ROOT_DIR>/bin/zowe-configure-instance.sh -c <PATH_TO_INSTANCE_DIR> -g <GROUP>
```

Reviewing the \(\text{instance.env}\) file

To operate Zowe, a number of zFS folders need to be located for prerequisites on the platform. Default values are selected when you run `zowe-configure-instance.sh`. You might want to modify the values.

Component groups

`LAUNCH_COMPONENT_GROUPS`: This is a comma-separated list of which z/OS microservice groups are started when Zowe launches.

- `GATEWAY` will start the API mediation layer that includes the API catalog, the API gateway, and the API discovery service. These three address spaces are Apache Tomcat servers and uses the version of Java on z/OS as determined by the `JAVA_HOME` value.
- `DESKTOP` will start the Zowe desktop that is the browser GUI for hosting Zowe applications such as the 3270 Terminal emulator or the File Explorer. The Zowe desktop is a node application and uses the version specified by the `NODE_HOME` value.
- Vendor products may extend Zowe with their own component group that they want to be lifecycled by the Zowe `ZWESVSTC` started task and run as a Zowe sub address space. To do this, specify the fully qualified directory provided by the vendor that contains their Zowe extension scripts. This directory will contain a `start.sh` script (required) that is called when the `ZWESVSTC` started task is launched, a `configure.sh` script (optional) that performs any configuration steps such as adding iFrame plug-ins to the Zowe desktop, and a `validate.sh` script (optional) that can be used to perform any pre-launch validation such as checking system prerequisites. For more information about how a vendor can extend Zowe with a sub address space, see the Onboarding Overview on page 211 section.

Component prerequisites

- `JAVA_HOME`: The path where 64-bit Java 8 or later is installed. Only needs to be specified if not already set as a shell variable. Defaults to `/usr/lpp/java/J8.0_64`. 

• **NODE_HOME**: The path to the Node.js runtime. Only needs to be specified if not already set as a shell variable.
• **ROOT_DIR**: The directory where the Zowe runtime is located. Defaults to the location of where `zowe-configure-instance` was executed.
• **ZOSMF_PORT**: The port used by z/OSMF REST services. Defaults to value determined through running `netstat`.
• **ZOSMF_HOST**: The host name of the z/OSMF REST API services.
• **ZOWE_EXPLORER_HOST**: The hostname of where the Explorer servers are launched from. Defaults to running `hostname -c`. Ensure that this host name is externally accessible from clients who want to use Zowe as well as internally accessible from z/OS itself.
• **ZOWE_IP_ADDRESS**: The IP address of your z/OS system which must be externally accessible to clients who want to use Zowe. This is important to verify for IBM Z Development & Test Environment and cloud systems, where the default that is determined through running `ping` and `dig` on z/OS return a different IP address from the external address.
• **APIML_ENABLE_SSO**: Define whether single sign-on should be enabled. Use a value of `true` or `false`. Defaults to `false`.

**Keystore configuration**

• **KEYSTORE_DIRECTORY**: This is a path to a zFS directory containing the certificate that Zowe uses to identify itself and encrypt HTTPS traffic to its clients accessing REST APIs or web pages. This also contains a truststore used to hold the public keys of any z/OS services that Zowe is communicating to, such as z/OSMF. The keystore directory must be created the first time Zowe is installed onto a z/OS system and it can be shared between different Zowe runtimes. For more information about how to create a keystore directory, see Configuring Zowe certificates on page 102.

**Address space names**

Individual address spaces for different Zowe instances and their subcomponents can be distinguished from each other in RMF records or SDSF views by specifying how they are named. Address space names are 8 characters long and made up of a prefix `ZOWE_PREFIX`, instance `ZOWE_INSTANCE` followed by an identifier for each subcomponent.

• **ZOWE_PREFIX**: This defines a prefix for Zowe address space STC names. Defaults to `ZWE`.
• **ZOWE_INSTANCE**: This is appended to the `ZOWE_PREFIX` to build up the address space name. Defaults to `1`.
• A subcomponent will be one of the following values:
  • **AC** - API ML Catalog
  • **AD** - API ML Discovery Service
  • **AG** - API ML Gateway
  • **DS** - App Server
  • **EF** - Explorer API Data Sets
  • **EJ** - Explorer API Jobs
  • **SZ** - ZSS Server
  • **UD** - Explorer UI Data Sets
  • **UJ** - Explorer UI Jobs
  • **UU** - Explorer UI USS

The STC name of the main started task is `ZOWE_PREFIX+ZOWE_INSTANCE+SV`.

**Example:**

```
ZOWE_PREFIX=ZWE
ZOWE_INSTANCE=X
```

the first instance of Zowe API ML Gateway identifier will be as follows:

```
ZWEXAG
```
**Note:** If the address space names are not assigned correctly for each subcomponents, check that the step Configure address space job naming on page 101 has been performed correctly for the z/OS user ID ZWESVUSR.

**Ports**

When Zowe starts, a number of its microservices need to be given port numbers that they can use to allow access to their services. The two most important port numbers are the GATEWAY_PORT which is for access to the API gateway through which REST APIs can be viewed and accessed, and ZOWE_ZLUX_SERVER_HTTPS_PORT which is used to deliver content to client web browsers logging in to the Zowe desktop. All of the other ports are not typically used by clients and used for intra-service communication by Zowe.

- **CATALOG_PORT**: The port the API catalog service will use.
- **DISCOVERY_PORT**: The port the discovery service will use.
- **GATEWAY_PORT**: The port the API gateway service will use. This port is used by REST API clients to access z/OS services through the API mediation layer, so should be accessible to these clients. This is also the port used to log on to the API catalog web page through a browser.
- **JOBS_API_PORT**: The port the jobs API service will use.
- **FILES_API_PORT**: The port the files API service will use.
- **JES_EXPLORER_UI_PORT**: The port the jes-explorer UI service will use.
- **MVS_EXPLORER_UI_PORT**: The port the mvs-explorer UI service will use.
- **USS_EXPLORER_UI_PORT**: The port the uss-explorer UI service will use.
- **ZOWE_ZLUX_SERVER_HTTPS_PORT**: The port used by the Zowe desktop. It should be accessible to client machines with browsers wanting to log on to the Zowe desktop.
- **ZOWE_ZSS_SERVER_PORT**: This port is used by the ZSS server.

**Note:** If all of the default port values are acceptable, the ports do not need to be changed. To allocate ports for the Zowe runtime servers, ensure that the ports are not in use.

To determine which ports are not available, follow these steps:

1. Display a list of ports that are in use with the following command:
   ```
   TSO NETSTAT
   ```

2. Display a list of reserved ports with the following command:
   ```
   TSO NETSTAT PORTLIST
   ```

**Terminal ports**

**Note:** Unlike the ports needed by the Zowe runtime for its Zowe Application Framework and z/OS Services which must be unused, the terminal ports are expected to be in use.

- **ZOWE_ZLUX_SSH_PORT**: The Zowe desktop contains an application VT Terminal which opens a terminal to z/OS inside the Zowe desktop web page. This port is the number used by the z/OS SSH service and defaults to 22. The USS command `netstat -b | grep SSHD1` can be used to display the SSH port used on a z/OS system.
- **ZOWE_ZLUX_TELNET_PORT**: The Zowe desktop contains an application 3270 Terminal which opens a 3270 emulator inside the Zowe desktop web page. This port is the number used by the z/OS telnet service and defaults to 23. The USS command `netstat -b | grep TN3270` can be used to display the telnet port used on a z/OS system.
- **ZOWE_ZLUX_SECURITY_TYPE**: The 3270 Terminal application needs to know whether the telnet service is using tls or telnet for security. The default value is blank for telnet.

**Extensions**

- **ZWEBAD_EXTERNAL_STATIC_DEF_DIRECTORIES**: Full USS path to the directory that contains static API Mediation Layer .yml definition files. For more information, see Add a definition in the API Mediation Layer in the Zowe runtime on page 235. Multiple paths should be semicolon separated. This value allows a Zowe instance to be configured so that the API Mediation Layer can be extended by third party REST API and web UI servers.
• **EXTERNAL_COMPONENTS**: For third-party extenders to add the full path to the directory that contains their component lifecycle scripts. For more information, see Zowe extensions on page 285.

**Installing and configuring the Zowe cross memory server (ZWESISTC)**

The Zowe cross memory server provides privileged cross-memory services to the Zowe Desktop and runs as an APF-authorized program. The same cross memory server can be used by multiple Zowe desktops. You must install, configure, and launch the cross memory server if you want to use the Zowe desktop. Otherwise, you can skip this step.

To install and configure the cross memory server, you must create or edit APF-authorized load libraries, program properties table (PPT) entries, and a parmlib. This requires familiarity with z/OS.

The cross memory server runtime artifacts, the JCL for the started tasks, the parmlib, and members containing sample configuration commands are installed in the **SZWESAMP** PDS SAMPLIB. The load modules for the cross memory server and an auxiliary server it uses are installed in the **SZWEAUTH** PDS load library. The location of these for a convenience build depends on the value of the `zowe-install.sh -h` argument, see Step 3: Choose a dataset HLQ for the SAMPLIB and LOADLIB on page 76. For an SMP/E installation, the location is the value of `$datasetPrefixIn` in the member `AZWE001.F1(ZWE3ALOC)`.

The cross memory server is a long running angel process server that runs under the started task **ZWESISTC** with the user ID **ZWESIUSR** and group of **ZWEADMIN**.

The **ZWESISTC** started task runs the load module **ZWESIS01**, serves the Zowe desktop that is running under the **ZWESVSTC** started task, and provides it with secure services that require elevated privileges, such as supervisor state, system key, or APF-authorization.

Under some situations in support of a Zowe extension, the cross memory server will start, control, and stop an auxiliary address space. This runs as a **ZWESASTC** started task that runs the load module **ZWESAUX**. Under normal Zowe operation, you will not see any auxiliary address spaces started. However, if you have installed a vendor product running on top of Zowe, this may use the auxiliary service so it should be configured to be launchable.

To install the cross memory server, take the following steps either Copy cross memory data set members manually on page 109 by using `cp` commands or use the supplied Copy cross memory data set members automatically on page 109 `zowe-install-xmem.sh` for an automated installation process.
Step 1: Copy the cross memory PROCLIB and load library

Copy cross memory data set members manually

1. Copy the load modules and add JCL to a PROCLIB:

   For the cross memory server to be started, its load modules need to be moved to an APF-authorized PDSE, and its JCL PROCLIB members moved to a PDS in the JES concatenation path.

   a. **Load modules** The cross memory server has two load modules, ZWESIS01 and ZWESAUX, provided in the PDS SZWEAUTH created during the installation of Zowe. To manually copy the files to a user-defined data set, you can issue the following commands:

```
    cp -X ZWESIS01 "//'<zwes_loadlib>(ZWESIS01)''
    cp -X ZWESAUX "//'<zwes_loadlib>(ZWESAUX)''
```

   Where `<zwes_loadlib>` is the name of the data set, for example ZWES.SISLOAD. The `<zwes_loadlib>` data set must be a PDSE due to language requirements.

   b. **Proc libraries** The cross memory server PROCLIB JCL is ZWESISTC and the auxiliary address space PROCLIB JCL is ZWESASTC.

   You must specify the `<zwes_loadlib>` data set where ZWESIS01 and ZWESAUX were copied to, in the STEPLIB DD statement of the two PROCLIB JCL members ZWESISTC and ZWESASTC respectively so that the appropriate version of the software is loaded correctly.

   Do not add the `<zwes_loadlib>` data set to the system LNKLST or LPALST concatenations.

2. Add a ZWESIP00 PARMLIB member for the ZWESISTC started task:

   When started, the ZWESISTC started task must find a valid ZWESIPxx PARMLIB member. The SZWESAMP PDS contains the member ZWESIP00 containing default configuration values. You can copy this member to your system PARMLIB data set, or allocate the default PDS data set ZWES.SISAMP that is specified in the ZWESISTC started task JCL.

Copy cross memory data set members automatically

Instead of the manual steps Copy cross memory data set members manually on page 109, a convenience script `<ROOT_DIR>/scripts/utils/zowe-install-xmem.sh` is shipped with Zowe to help with copying the cross memory and auxiliary address space PROCLIB members, the PARMLIB member, and the load libraries.

The script `zowe-install-xmem.sh -d <dataSetPrefix> -b <loadlib> -a <parmlib> [-r <proclib> -l <log_directory>]` has the following parameters:

- **-d `<dataSetPrefix>`** - Source PDS Prefix
  
  Data set prefix of the source PDS where .SZWESAMP(ZWESVSTC) was installed into.
  
  For an installation from a convenience build, this will be the value of `zowe-install.sh -h` when the build was installed. See Step 3: Choose a dataset HLQ for the SAMPLIB and LOADLIB on page 76
  
  For an SMP/E installation, this will be the value of `$datasetPrefixIn` in the member AZWE001.F1(ZWE3ALLOC).

- **-b `<loadlib>`** - Target DSN Load Library
  
  This is the data set name of the PDSE where members ZWESIS01 and ZWESAUX will be copied into. This must be an APF-authorized PDS.

- **-a `<parmlib>`** - Target DSN for PARMLIB
  
  This is the data set name of where the PARMLIB ZWESIP00 will be placed.

- **-r `<proclib>`** - Target DSN for PROCLIB (optional)
  
  Target PROCLIB PDS where ZWESVSTC will be placed. If parameter is omitted the script scans the JES PROCLIB concatenation path and uses the first data set where the user has write access.
• `-l <log_directory>` - Log directory (optional)
  Overrides the default log output directory of `/global/zowe/logs`, if it is writable, or `~/zowe/logs`.

**Example:**
Executing the command `zowe-install-xmem.sh -d MYUSERID.ZWE -b SYS1.IBM.ZIS.SZISLOAD -a SYS1.IBM.PARMLIB -r USER.PROCLIB` copies:
- the load modules `MYUSERID.ZWE.SZWEAUTH(ZWESIS01)` and `MYUSERID.ZWE.SZWEAUTH(ZWESAUX)` to the load library `SYS.IBM.ZIS.SZISLOAD`
- the `PARMLIB` member `MYUSERID.ZWE.SZWESAMP(ZWESIP00)` to `SYS1.IBM.PARMLIB(ZWESIP00)`
- the `PROCLIB` member `MYUSERID.ZWE.SZWESAMP(ZWESISTC)` to `USER.PROCLIB(ZWESISTC)`
  and `MYUSERID.ZWE.SZWESAMP(ZWESASTC)` to `USER.PROCLIB(ZWESASTC)`

The user ID `ZWESIUSR` that is assigned to the cross memory server started tasks must have a valid OMVS segment
and read access to the data sets where the load library and `PROCLIB` are held. The cross memory server loads
the modules to LPA for its PC-cp services.

**Step 2: Add PPT entries to the system PARMLIB**
The cross memory server and its auxiliary address spaces must run in key 4 and be non-swappable. For the server to
start in this environment, add the following PPT entries for the server and address spaces to the SCHEDxx member of
the system PARMLIB.

```
PPT PGMNAME(ZWESIS01) KEY(4) NOSWAP
```
```
PPT PGMNAME(ZWESAUX) KEY(4) NOSWAP
```

The PDS member `ZWESAMP(ZWESISCH)` contains the PPT lines for reference.
Then, issue the following command to make the SCHEDxx changes effective:
```
/SET SCH=xx
```

**Step 3: Add the load libraries to the APF authorization list**
Because the cross memory server provides privileges services, its load libraries require APF-authorization. To check
whether a load library is APF-authorized, you can issue the following TSO command:

```
D PROG,APF,DSNAME=ZWES.SISLOAD
```
where the value of `DSNAME` is the name of the data set that contains the ZWESIS01 and ZWESAUX load modules.
To dynamically add a load library to the APF list if the load library is not SMS-managed, issue the following TSO
command:
```
SETPROG APF,ADD,DSNAME=ZWES.SISLOAD,VOLUME=volser
```
If the load library is SMS-managed, issue the following TSO command:
```
SETPROG APF,ADD,DSNAME=ZWES.SISLOAD,SMS
```
where the value of `DSNAME` is the name of the data set that contains the ZWESIS01 and ZWESAUX load modules.
If you want to authorize the loadlib permanently, then add the following statement to `SYS1.PARMLIB(PROGxx)` or equivalent

The PDS member `ZWESAMP(ZWESIMPRG)` contains the SETPROG statement for reference.
Step 4: Configure SAF

The cross memory server performs a sequence of SAF checks to protect its services from unauthorized callers. To do this, it uses the FACILITY class and a ZWES.IS entry. Valid callers must have READ access to the ZWES.IS profile. Those callers include the STC user ZWESVUSR under which the ZWESVSTC started task runs. It is recommended that you also grant READ access to the STC user under which the ZWESASTC started task runs which is ZWESIUSR.

The commands required to configure SAF for the cross memory server are included in a JCL member ZWESSECUR that is delivered with Zowe, see Configuring z/OS system.

Step 5: Configure security environment switching

When responding to API requests, the Zowe desktop node API server running under USS must be able to change the security environment of its process to associate itself with the security context of the logged in user. This is called impersonation.

For commands required to configure impersonation, see Configure security environment switching on page 99.

Starting and stopping the cross memory server on z/OS

The cross memory server is run as a started task from the JCL in the PROCLIB member ZWESISTC. It supports reusable address spaces and can be started through SDSF with the operator start command with the REUSASID=YES keyword:

```
/S ZWESISTC,REUSASID=YES
```

The ZWESISTC task starts and stops the ZWESSTC task as needed. Do not start the ZWESASTC task manually.

To end the Zowe cross memory server process, issue the operator stop command through SDSF:

```
/P ZWESISTC
```

Note:

The starting and stopping of the ZWESVSTC for the main Zowe servers is independent of the ZWESISTC cross memory server that is an angel process. If you are running more than one ZWESVSTC instance on the same LPAR, then these will be sharing the same ZWESISTC cross memory server. Stopping ZWESISTC will affect the behavior of all Zowe servers on the same LPAR that use the same cross-memory server name, for example ZWESIS_STD. The Zowe Cross Memory Server is designed to be a long-lived address space. There is no requirement to recycle regularly. When the cross-memory server is started with a new version of the ZWESIS01 load module, it abandons its current load module instance in LPA and loads the updated version.

To diagnose problems that may occur with the Zowe ZWESVSTC being able to attach to the ZWESISTC cross memory server, a log file zssServer-yyyy-mm-dd-hh-mm.log is created in the instance directory /logs folder each time a Zowe ZWESVSTC instance is started. More details on diagnosing errors can be found in Cannot log in to the Zowe Desktop on page 316.

Installing the Zowe started task (ZWESVSTC)

Zowe has a number of runtimes on z/OS: the z/OS Service microservice server, the Zowe Application Server, and the Zowe API Mediation Layer microservices. A single PROCLIB ZWESVSTC is used to start all of these microservices. This member is installed by Zowe into the data set SAMPLIB SZWESAMP during the installation or either a convenience build or SMP/E. This topic describes how to configure the z/OS runtime in order to launch the Zowe started task.

Step 1: Copy the PROCLIB member ZWESVSTC

When the Zowe runtime is launched, it is run under a z/OS started task (STC) with the PROCLIB member named ZWESVSTC. A sample PROCLIB is created during installation into the PDS SZWESAMP. To launch Zowe as a started task, you must copy the member ZWESVSTC to a PDS that is in the proclib concatenation path.
If your site has its own technique for PROCLIB creation, you may follow this and copy the ZWESVSTC as-is. If you want to create a pipeline or automate the PROCLIB copying, you can use a convenience script zowe-install-proc.sh that is provided in the <ROOT_DIR>/scripts/utils folder.

The script zowe-install-proc.sh -d <dataSetPrefix> [-r <proclib> -l <log_directory>] has the following parameters:

- **-d <dataSetPrefix>** - Source PDS Prefix
  
  Dataset prefix of the source PDS where .SZWESAMP (ZWESVSTC) was installed into.

  For an installation from a convenience build, this will be the value of the -h argument when zowe-install.sh was executed.

  For an SMP/E installation, this will be the value of $datasetPrefixIn in the member AZWE001.F1 (ZWE3ALOC).

- **-r <proclib>** - Target PROCLIB PDS (optional)
  
  Target PROCLIB PDS where ZWESVSTC will be placed. If parameter is omitted, the script scans the JES PROCLIB concatenation path and uses the first data set where the user has write access

- **-l <log_directory>** - Log directory (optional)
  
  Overrides the default log output directory of /global/zowe/logs, if it is writable, or ~/zowe/logs.

**Example**

Executing the command zowe-install-proc.sh -d MYUSERID.ZWE -r USER.PROCLIB copies the PDS member MYUSERID.ZWE.SZWESAMP (ZWESVSTC) to USER.PROCLIB(ZWESVSTC)

**Step 2: Configure ZWESVSTC to run under the correct user ID**

The ZWESVSTC must be configured as a started task (STC) under the ZWESVUSR user ID with the administrator user ID of ZWEADMIN. The commands to create the user ID and group is supplied in the PDS member ZWESECUR, see Configuring the z/OS system for Zowe on page 96. To associate the ZWESVSTC started task with the user ID and group see Configuring the z/OS system for Zowe on page 96. This step will be done once per z/OS environment by a system programmer who has sufficient security privileges.

**Step 3: Launch the ZWESVSTC started task**

You can launch the Zowe started task in two ways.

**Option 1: Starting Zowe from a USS shell**

To launch the ZWESVSTC started task, run the zowe-start.sh script from a USS shell. This reads the configuration values from the zowe-instance.env file in the Zowe instance directory.

```
cd <ZOWE_INSTANCE_DIR>/bin
./zowe-start.sh
```

where,

<ZOWE_INSTANCE_DIR> is the directory where you set the instance directory to. This script starts ZWESVSTC for you so you do not have to log on to TSO and use SDSF.

**Option 2: Starting Zowe with a /s TSO command**

You can use SDSF to start Zowe.

If you issue the SDSF command /S ZWESVSTC, it will fail because the script needs to know the instance directory containing the configuration details.

If you have a default instance directory you want you always start Zowe with, you can tailor the JCL member ZWESVSTC at this line

```
//ZWESVSTC PROC INSTANCE='{{instance_directory}}'
```
to replace the instance_directory with the location of the Zowe instanceDir that contains the configurable Zowe instance directory.

If the JCL value instance-directory is not specified in the JCL, in order to start the Zowe server from SDSF, you will need to add the INSTANCE parameter on the START command when you start Zowe in SDSF:

```
/S ZWESVSTC,INSTANCE='$ZOWE_INSTANCE_DIR',JOBNAME='ZWEXSV'
```

The JOBNAME='ZWEXSV' is optional and the started task will operate correctly without it, however having it specified ensures that the address spaces will be prefixed with ZWEXSV which makes them easier to find in SDSF or locate in RMF records.

### Stopping the ZWESVSTC PROC

To stop the Zowe server, the ZWESVSTC PROC needs to be ended. Run the zowe-stop.sh script at the Unix Systems Services command prompt that is in the zowe instance directory used to start the Zowe started task:

```
cd $ZOWE_INSTANCE_DIR/bin
./zowe-stop.sh
```

where `<ZOWE_INSTANCE_DIR>` is the directory where you set the instance directory to.

When you stop ZWESVSTC, you might get the following error message:

```
IEE842I ZWESVSTC DUPLICATE NAME FOUND- REENTER COMMAND WITH 'A='
```

This error results when there is more than one started task named ZWESVSTC. To resolve the issue, stop the required ZWESVSTC instance by issuing the following commands:

```
/C ${ZOWE_PREFIX}${ZOWE_INSTANCE}SV,A=asid
```

Where ZOWE_PREFIX and ZOWE_INSTANCE are specified in your configuration (and default to ZWE and 1) and you can obtain the asid from the value of A=asid when you issue the following commands:

```
/D A,${ZOWE_PREFIX}${ZOWE_INSTANCE}SV
```

### Verifying Zowe installation on z/OS

After the Zowe™ started task ZWESVSTC is running, follow the instructions in the following sections to verify that the components are functional.

- Verifying Zowe Application Framework installation on page 113
- Verifying API Mediation installation on page 114
- Verifying z/OS Services installation

**Note:** Not all components may have been started. Which components have been started depends on your setting of the variable LAUNCH_COMPONENT_GROUPS in the instance.env file. If you defined the value GATEWAY, the API Mediation Layer and z/OS Services are started. If you defined the value DESKTOP, the Zowe Application Framework (also known as Zowe desktop) is started. For more information, see Component groups on page 105.

### Verifying Zowe Application Framework installation

If the Zowe Application Framework is installed correctly, you can open the Zowe Desktop from a supported browser.

From a supported browser, open the Zowe Desktop at `https://myhost:httpsPort`

where,

- `myHost` is the host on which you installed the Zowe Application Server.
- **httpsPort** is the port number value ZOWE_ZLUX_SERVER_HTTPS_PORT in instance.env. For more information, see [Ports](#) on page 107.

  For example, if the Zowe Application Server runs on host `myhost` and the port number that is assigned to ZOWE_ZLUX_SERVER_HTTPS_PORT is 12345, you specify `https://myhost:12345`. The web desktop uses page direct to the actual initial page which is `https://myhost:12345/ZLUX/plugins/org.zowe.zlux.bootstrap/web/index.html`. If the redirect fails, try the full URL.

  If the desktop appears but you are unable to log on, check [Cannot log in to the Zowe Desktop](#) on page 316 for troubleshooting tips.

**Verifying API Mediation installation**

Use your preferred REST API client to review the value of the status variable of the API Catalog service that is routed through the API Gateway using the following URL:

```
https://myhost:httpsPort/api/v1/apicatalog/application/health
```

where,

- **myHost** is the host on which you installed the Zowe Application Server.
- **httpsPort** is the port number value GATEWAY_PORT in instance.env. For more information, see [Ports](#) on page 107.

**Example:**

The following example illustrates how to use the **curl** utility to invoke API Mediation Layer endpoint and the **grep** utility to parse out the response status variable value

```
$ curl -v -k --silent https://myhost:httpsPort/api/v1/apicatalog/application/health 2>&1 | grep -Po '(?<="status":")[^\"]+"[^\"]+"')
```

```
UP
```

The response **UP** confirms that API Mediation Layer is installed and is running properly.

**Verifying z/OS Services installation**

You can verify the installation of z/OS Services from an internet browser by entering the following case-sensitive URL:

```
https://hostName:gatewayPort/api/v1/jobs?prefix=*
```

where,

- **gatewayPort** is the port number that is assigned to GATEWAY_PORT in the instance.env file used to launch Zowe. For more information, see [Ports](#) on page 107.

**Zowe Auxiliary Address space**

The cross memory server runs as a started task `ZWESISTC` that uses the load module `ZWESIS01`.

In some use cases, the Zowe cross memory server has to spawn child address spaces, which are known as auxiliary (AUX) address spaces. The auxiliary address spaces run as the started task `ZWESASTC` using the load module `ZWESAUX` and are started, controlled, and stopped by the cross memory server.

An example of when an auxiliary address space is used is for a system service that requires supervisor state but cannot run in cross-memory mode. The service can be run in an AUX address space which is invoked by the Cross Memory Server acting as a proxy for unauthorized users of the service.

Do not install the Zowe auxiliary address space unless a Zowe extension product's installation guide explicitly asks for it to be done. This will occur if the extension product requires services of Zowe that cannot be performed by the cross memory server and an auxiliary address space needs to be started.
A default installation of Zowe does not require auxiliary address spaces to be configured.
You do not start or stop the ZWESASTC manually.

Uninstalling Zowe from z/OS

You can uninstall Zowe™ from z/OS if you no longer need to use it.

Follow these steps:

1. Stop the Zowe started task which stops all of its microservices by using the following command:

   ```bash
   /C ${ZOWE_PREFIX}${ZOWE_INSTANCE}SV
   ```

   Where ZOWE_PREFIX and ZOWE_INSTANCE are specified in your configuration (and default to ZWE and 1), see Address space names on page 106

   After Zowe has been stopped its subcomponents will end which include the API Mediation Layer and the Zowe desktop.

2. Delete the ZWESVSTC member from your system PROCLIB data set.

   To do this, you can issue the following TSO DELETE command from the TSO READY prompt or from ISPF option 6:

   ```bash
   delete 'your.zowe.proclib(zwesvstc)'
   ```

   Alternatively, you can issue the TSO DELETE command at any ISPF command line by prefixing the command with TSO:

   ```bash
   tso delete 'your.zowe.proclib(zwesvstc)'
   ```

   To query which PROCLIB data set that ZWESVSTC is put in, you can view the SDSF JOB log of ZWESVSTC and look for the following message:

   ```text
   IEFC001I PROCEDURE ZWESVSTC WAS EXPANDED USING SYSTEM LIBRARY your.zowe.proclib
   ```

   If no ZWESVSTC JOB log is available, issue the `/SD PROCLIB` command at the SDSF COMMAND INPUT line and BROWSE each of the DNAME=some.jes.proclib output lines in turn with ISPF option 1, until you find the first data set that contains member ZWESVSTC. Then, issue the DELETE command as shown above.

   After you have removed ZWESVSTC from the PROCLIB data set it will no longer be possible to start Zowe instances.

3. Remove the USS folders containing the Zowe artifacts

   Remove the USS folders containing the Zowe runtime, the Zowe keystore-directory, and the Zowe instance directories.

4. Reverse the z/OS security and environment updates from ZWESSECUR job

   As part of installing Zowe the z/OS environment will have been altered to allow Zowe to operate, see Configuring the z/OS System for Zowe. You may leave the environment configured which allows you to install and operate a Zowe instance at a point in the future, or you may undo the configuration steps to your z/OS environment. A JCL member ZWENOSEC is provided with Zowe that contains the commands needed to reset a z/OS environment and undo the steps that were performed in ZWESSECUR when the environment was configured for Zowe operation.
Installing Zowe CLI

Installing Zowe CLI

Install Zowe™ CLI on your computer.

Tip: If you are familiar with command-line tools and want to get started using Zowe CLI quickly, see Zowe CLI quick start on page 40. You can learn about new CLI features in the Release notes on page 19.

Methods to install Zowe CLI

Use one of the following methods to install Zowe CLI.

• Installing Zowe CLI from a local package on page 116
• Installing Zowe CLI from an online registry on page 117

If you encounter problems when you attempt to install Zowe CLI, see Troubleshooting Zowe CLI on page 324.

Installing Zowe CLI from a local package

If you do not have internet access at your site, use the following method to install Zowe CLI from a local package.

Follow these steps:

1. Address the following software requirements for the core CLI:
   • Install Node.js V8.0 or higher LTS versions
     Tip: You might need to restart the command prompt after installing Node.js. Issue the command node --version to verify that Node.js is installed.
     • Verify that you have Node Package Manager (npm) that is compatible with your version of Node.js. For a list of compatible versions, see Node.js Previous Releases.
       Tip: npm is included with the Node.js installation. Issue the command npm --version to verify the version of npm that is installed.
   2. (Linux only) Address the following software requirements for Secure Credential Storage:
      • (Graphical Linux) Install gnome-keyring and libsecret on your computer.
      • (Headless Linux) Follow the procedure documented in the SCS plug-in Readme.
   3. Navigate to Zowe.org Downloads and click the CLI Core button to download the core package. The "core" includes Zowe CLI and Secure Credential Store, which enhances security by encrypting your username and password.
      A file named zowe-cli-package-v.r.m.zip is downloaded to your computer
   4. (Optional) Click the CLI Plugins button to download the optional plugins.
      A file named zowe-cli-plugins-v.r.m.zip is downloaded to your computer.
   5. Unzip the contents of zowe-cli-package-v.r.m.zip (and optionally zowe-cli-plugins-v.r.m.zip) to a preferred location on your computer.
6. Open a command-line window. Issue the following commands in sequence against the extracted directory to install core Zowe CLI on your computer:

```bash
npm install -g zowe-cli.tgz
zowe plugins install secure-credential-store-for-zowe-cli.tgz
```

**Notes:**
- If the command returns an **EACCESS** error, refer to Resolving **EACCESS** permissions errors when installing packages globally in the npm documentation.
- On Linux, you might need to prepend `sudo` to your `npm` commands. For more information, see Troubleshooting Zowe CLI on page 324.

7. *(Optional)* Address the Software requirements for Zowe CLI plug-ins on page 180. You can install most plug-ins without meeting the requirements, but they will not function until you configure the back-end APIs. The IBM Db2 plug-in requires Installing on page 186.

8. *(Optional)* Issue the following command to install each available plug-in:

```bash
zowe plugins install cics-for-zowe-cli.tgz db2-for-zowe-cli.tgz zos-ftp-for-zowe-cli.tgz ims-for-zowe-cli.tgz mq-for-zowe-cli.tgz
```

**Important:** Ensure that you meet the Software requirements for Zowe CLI plug-ins on page 180. You can install most plug-ins without meeting the requirements, but they will not function until you configure the back-end APIs. The IBM Db2 plug-in requires Installing on page 186.

Zowe CLI is installed on your computer. Issue the `zowe --help` command to view a list of available commands. For information about how to connect the CLI to the mainframe (using command-line options, user profiles, or environment variables), see Defining Zowe CLI connection details on page 136. You can also test your connection to z/OSMF with or without a profile.

**Installing Zowe CLI from an online registry**

If your computer is connected to the Internet, you can use the following method to install Zowe CLI from an npm registry.

**Follow these steps:**

1. Address the following software requirements for the core CLI:
   - Install Node.js V8.0 or higher LTS versions
     **Tip:** You might need to restart the command prompt after installing Node.js. Issue the command `node --version` to verify that Node.js is installed.
     - Verify that you have **Node Package Manager (npm)** that is compatible with your version of Node.js. For a list of compatible versions, see Node.js Previous Releases.
       **Tip:** npm is included with the Node.js installation. Issue the command `npm --version` to verify the version of npm that is installed.
   - *(Linux only)* Address the following software requirements for Secure Credential Storage:
     - *(Graphical Linux)* Install `gnome-keyring` and `libsecret` on your computer.
     - *(Headless Linux)* Follow the procedure documented in the SCS plug-in Readme.
3. Issue the following commands in sequence to install the core from the public npm registry. The "core" includes Zowe CLI and Secure Credential Store, which enhances security by encrypting your username and password.

```sh
npm install -g @zowe/cli@zowe-v1-lts

zowe plugins install @zowe/secure-credential-store-for-zowe-cli@zowe-v1-lts
```

Notes:
- If the command returns an EACCESS error, refer to Resolving EACCESS permissions errors when installing packages globally in the npm documentation.
- On Linux, you might need to prepend `sudo` to your `npm` commands. For more information, see Troubleshooting Zowe CLI on page 324.

4. (Optional) Address the Software requirements for Zowe CLI plug-ins on page 180. You can install most plug-ins without meeting the requirements, but they will not function until you configure the back-end APIs. The IBM Db2 plug-in requires Installing on page 186.

5. (Optional) To install all available plug-ins to Zowe CLI, issue the following command:

```sh
zowe plugins install @zowe/cics-for-zowe-cli@zowe-v1-lts @zowe/db2-for-zowe-cli@zowe-v1-lts @zowe/ims-for-zowe-cli@zowe-v1-lts @zowe/mq-for-zowe-cli@zowe-v1-lts @zowe/zos-ftp-for-zowe-cli@zowe-v1-lts
```

After you install and configure Zowe CLI, issue the `zowe --help` command to view a list of available commands. For information about how to connect the CLI to the mainframe (using command-line options, user profiles, or environment variables), see Defining Zowe CLI connection details on page 136. You can also test your connection to z/OSMF with or without a profile.

**Updating Zowe CLI**

Zowe™ CLI is updated continuously. You can update Zowe CLI to a more recent version using online registry method or the local package method. However, you can only update Zowe CLI using the method that you used to install Zowe CLI.

- Migrating to Long-term Support (LTS) version on page 118
- Identify the currently installed version of Zowe CLI on page 119
- Identify the currently installed versions of Zowe CLI plug-ins on page 119
- Update Zowe CLI from the online registry on page 119
- Update or revert Zowe CLI to a specific version on page 119
- Update Zowe CLI from a local package on page 119

**Migrating to Long-term Support (LTS) version**

If you have an @lts-incremental version of Zowe CLI (Zowe v1.0.x - v1.8.x), you can update to @zowe-v1-lts (LTS version) to leverage new functionality and plug-ins.

Follow these steps:

1. (Optional) Copy the contents of `~/.zowe/profiles` or `%homepath%\.zowe\profiles` to another directory on your computer to preserve your existing user profiles (zosmf, cics, db2, etc.).
2. Delete the `~/.zowe/plugins` or `%homepath%\.zowe\plugins` directory to uninstall all plug-ins.
3. Uninstall the pre-LTS version of core CLI. Issue the following command:

```sh
npm uninstall -g @brightside/core
```

Note: You might receive an ENOENT error when issuing this command if you installed Zowe CLI from a local package (.tgz) and the package was moved from its original location. In the event that you receive the error, open an issue in the Zowe CLI GitHub repository.
4. Install the most recent @zowe-v1-lts version CLI and optional plug-ins. For more information, see Installing Zowe CLI on page 116.

5. (Optional) Reestablish your user profiles. Move the profile configuration files that you saved in Step 1 into the ~/.zowe/profiles or %homepath%\zowe\profiles folder on your computer.

You updated to the Zowe CLI LTS version!

Ensure that you review the Release notes on page 19, which describes Notable Changes in this version. We recommend issuing familiar commands and running scripts to ensure that your profiles/scripts are compatible. You might need to take corrective action to address the breaking changes.

Identify the currently installed version of Zowe CLI

Issue the following command:

```
zowe -V
```

Identify the currently installed versions of Zowe CLI plug-ins

Issue the following command:

```
zowe plugins list
```

Update Zowe CLI from the online registry

You can update Zowe CLI to the latest version from the online registry on Windows, Mac, and Linux computers.

Note: The following steps assume that you previously installed the CLI as described in Installing Zowe CLI from an online registry on page 117.

Follow these steps:

1. To update Zowe CLI to the most recent @zowe-v1-lts version, issue the following command:

   ```
   npm install -g @zowe/cli@zowe-v1-lts
   ```

2. To update existing plug-ins and install new plug-ins, issue the following command:

   ```
   zowe plugins install @zowe/cics-for-zowe-cli@zowe-v1-lts @zowe/db2-for-zowe-cli@zowe-v1-lts @zowe/ims-for-zowe-cli@zowe-v1-lts @zowe/mq-for-zowe-cli@zowe-v1-lts @zowe/zos-ftp-for-zowe-cli@zowe-v1-lts @zowe/secure-credential-store-for-zowe-cli@zowe-v1-lts
   ```

3. Recreate any user profiles that you created before you updated to the latest version of Zowe CLI.

Update or revert Zowe CLI to a specific version

Optionally, you can update Zowe CLI (or revert) to a known version. The following example illustrates the syntax to update Zowe CLI to version 6.1.2:

```
npm install -g @zowe/cli@6.1.2
```

Update Zowe CLI from a local package

To update Zowe CLI from an offline (.tgz) local package, uninstall your current package then reinstall from a new package using the Install from a Local package instructions. For more information, see Uninstalling Zowe CLI on page 119 and Installing Zowe CLI from a local package on page 116.

Important! Recreate any user profiles that you created before the update.

Uninstalling Zowe CLI

You can uninstall Zowe™ CLI from the desktop if you no longer need to use it.
**Important!** The uninstall process does not delete the profiles and credentials that you created when using the product from your computer. To delete the profiles from your computer, delete them before you uninstall Zowe CLI.

The following steps describe how to list the profiles that you created, delete the profiles, and uninstall Zowe CLI.

**Follow these steps:**

1. Open a command-line window.
   - **Note:** If you do not want to delete the Zowe CLI profiles from your computer, go to Step 5.

2. List all profiles that you created for a Zowe CLI command groups on page 176 by issuing the following command:

   ```
   zowe profiles list <profileType>
   ```

   **Example:**

   ```
   $ zowe profiles list zosmf
   The following profiles were found for the module zosmf:
   'SMITH-123' (DEFAULT)
   smith-123@SMITH-123-W7 C:\Users\SMITH-123
   $ 
   ```

3. Delete all of the profiles that are listed for the command group by issuing the following command:
   - **Tip:** For this command, use the results of the `list` command.
   - **Note:** When you issue the `delete` command, it deletes the specified profile and its credentials from the credential vault in your computer's operating system.

   ```
   zowe profiles delete <profileType> <profileName> --force
   ```

   **Example:**

   ```
   zowe profiles delete zosmf SMITH-123 --force
   ```

4. Repeat Steps 2 and 3 for all Zowe CLI command groups and profiles.

5. Uninstall Zowe CLI by issuing the following command:

   ```
   npm uninstall --global @zowe/cli
   ```

   **Note:** You might receive an `ENOENT` error when issuing this command if you installed Zowe CLI from a local package (.tgz) and the package was moved from its original location. In the event that you receive the error, open an issue in the Zowe CLI GitHub repository.

   The uninstall process removes all Zowe CLI installation directories and files from your computer.

6. Delete the `~/.zowe` or `%homepath%\.zowe` directory on your computer. The directory contains the Zowe CLI log files and other miscellaneous files that were generated when you used the product.
   - **Tip:** Deleting the directory does not harm your computer.

---

**Advanced Zowe configuration**

**Zowe Application Framework configuration**

After you install Zowe™, you can optionally configure the Zowe Application Framework as a Mediation Layer client, configure connections for the terminal application plug-ins, or modify the Zowe Application Server and Zowe System Services (ZSS) configuration, as needed.
Configuring the framework as a Mediation Layer client

For simpler Zowe administration and better security, you can install an instance of the Zowe Application Framework as an API Mediation Layer client.

This configuration is simpler to administer because the framework servers are accessible externally through a single port. It is more secure because you can implement stricter browser security policies for accessing cross-origin content.

You must use SSL certificates to configure the Zowe Application Server to communicate with the SSL-enabled Mediation Layer. Those certificates were created during the Zowe installation process, and are located in the $ROOT_DIR/components/app-server/share/zlux-app-server/defaults/serverConfig directory.

Enabling the Application Server to register with the Mediation Layer

When you install Zowe v1.8.0 or later, the Application Server automatically registers with the Mediation Layer.

For earlier releases, you must register the Application Server with the Mediation Layer manually. Refer to previous release documentation for more information.

Accessing the Application Server

To access the Application Server through the Mediation Layer, use the Mediation Layer gateway server hostname and port. For example, when accessed directly, this is Zowe Desktop URL: https://<appservername_port>/ZLUX/plugins/org.zowe.zlux.bootstrap/web/index.html

The port number for the Zowe Desktop is the value of the ZOWE_ZLUX_SERVER_HTTPS_PORT variable in the zowe-instance.env file in the instance directory, see Creating and configuring the Zowe instance directory on page 104.

When accessed through the API Mediation Layer, this is the Zowe Desktop URL: https://<gwsname_port>/ui/v1/zlux/ZLUX/plugins/org.zowe.zlux.bootstrap/web/index.html

The port number for the API Mediation Layer is the value of the GATEWAY_PORT variable in the zowe-instance.env file in the instance directory.

Setting up terminal application plug-ins

Follow these optional steps to configure the default connection to open for the terminal application plug-ins.

Setting up the TN3270 mainframe terminal application plug-in

_defaultTN3270.json is a file in tn3270-ng2/, which is deployed during setup. Within this file, you can specify the following parameters to configure the terminal connection:

```
  "host": <hostname>
  "port": <port>
  "security": { 
    type: "telnet" or "tls"
  } 
```

Setting up the VT Terminal application plug-in

_defaultVT.json is a file in vt-ng2/, which is deployed during setup. Within this file, you can specify the following parameters to configure the terminal connection:

```
  "host":<hostname>
  "port":<port>
  "security": { 
    type: "telnet" or "ssh"
  } 
```
Configuration file

The Zowe App Server and ZSS rely on many required or optional parameters to run, which includes setting up networking, deployment directories, plugin locations, and more.

For convenience, the Zowe Application Server and ZSS read from a JSON file with a common structure. ZSS reads this file directly as a startup argument, while the Zowe Application Server (as defined in the zlux-server-framework repository) accepts several parameters. The parameters are intended to be read from a JSON file through an implementer of the server, such as the example in the zlux-app-server repository (the lib/zluxServer.js file). The file accepts a JSON file that specifies most, if not all, of the parameters needed. Other parameters can be provided through flags, if needed.

For an instance, the configuration file is located at and can be edited at $INSTANCE_DIR/workspace/app-server/serverConfig/server.json. The defaults from which that file is generated are located at $ROOT_DIR/components/app-server/share/zlux-app-server/defaults/serverConfig/server.json.

Note: All examples are based on the zlux-app-server repository defaults.

Network configuration

Note: The following attributes are to be defined in the server's JSON configuration file.

The App Server can be accessed over HTTP and/or HTTPS, provided it has been configured for either.

HTTP

To configure the server for HTTP, complete these steps:

1. Define an attribute `http` within the top-level `node` attribute.
2. Define `port` within `http`. Where `port` is an integer parameter for the TCP port on which the server will listen.
   Specify 80 or a value between 1024-65535.

HTTPS

For HTTPS, specify the following parameters:

1. Define an attribute `https` within the top-level `node` attribute.
2. Define the following within `https`:
   - `port`: An integer parameter for the TCP port on which the server will listen. Specify 443 or a value between 1024-65535.
   - `certificates`: An array of strings, which are paths to PEM format HTTPS certificate files.
   - `keys`: An array of strings, which are paths to PEM format HTTPS key files.
   - `pfx`: A string, which is a path to a PFX file which must contain certificates, keys, and optionally Certificate Authorities.
   - `certificateAuthorities` (Optional): An array of strings, which are paths to certificate authorities files.
   - `certificateRevocationLists` (Optional): An array of strings, which are paths to certificate revocation list (CRL) files.

Note: When using HTTPS, you must specify `pfx`, or both `certificates` and `keys`.

Network example

In the example configuration, both HTTP and HTTPS are specified:

```
"node": {  
  "https": {  
    "ipAddresses": ["0.0.0.0"],  
    "port": 8544,  
    //pfx (string), keys, certificates, certificateAuthorities, and certificateRevocationLists are all valid here.  
    "keys": ["../defaults/serverConfig/server.key"],  
    "certificates": ["../defaults/serverConfig/server.cert"]  
  }  
```

Configuration Directories

When running, the App Server will access the server's settings and read or modify the contents of its resource storage. All of this data is stored within a hierarchy of folders which correspond to scopes:

- **Product**: The contents of this folder are not meant to be modified, but used as defaults for a product.
- **Site**: The contents of this folder are intended to be shared across multiple App Server instances, perhaps on a network drive.
- **Instance**: This folder represents the broadest scope of data within the given App Server instance.
- **Group**: Multiple users can be associated into one group, so that settings are shared among them.
- **User**: When authenticated, users have their own settings and storage for the Apps that they use.

These directories dictate where the Configuration Dataservice will store content.

Directories example

```javascript
// All paths relative to zlux-app-server/lib
// In real installations, these values will be configured during the install.
"productDir":"..//defaults",
"siteDir":"//home//myuser//.zowe//workspace//app-server//site",
"instanceDir":"//home//myuser//.zowe//workspace//app-server",
"groupsDir":"//home//myuser//.zowe//workspace//app-server//groups",
"usersDir":"//home//myuser//.zowe//workspace//app-server//users",
```

Old defaults

Prior to Zowe release 1.8.0, the location of the configuration directories were initialized to be within the `zlux-app-server` folder unless otherwise customized. 1.8.0 has backwards compatibility for the existence of these directories, but they can and should be migrated to take advantage of future enhancements.

<table>
<thead>
<tr>
<th>Folder</th>
<th>New Location</th>
<th>Old Location</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>productDir</td>
<td>zlux-app-server/defaults</td>
<td>zlux-app-server/deploy/product</td>
<td>Official installs place zlux-app-server within &lt;ROOT_DIR&gt;/components/app-server/share</td>
</tr>
<tr>
<td>siteDir</td>
<td>&lt;INSTANCE_DIR&gt;/workspace/app-server/site</td>
<td>zlux-app-server/deploy/site</td>
<td>INSTANCE_DIR is ~/.zowe if not otherwise defined. Site is placed within instance due to lack of SITE_DIR as of 1.8</td>
</tr>
<tr>
<td>instanceDir</td>
<td>&lt;INSTANCE_DIR&gt;/workspace/app-server</td>
<td>zlux-app-server/deploy/instance</td>
<td></td>
</tr>
<tr>
<td>groupsDir</td>
<td>&lt;INSTANCE_DIR&gt;/workspace/app-server/groups</td>
<td>zlux-app-server/deploy/instance/groups</td>
<td></td>
</tr>
<tr>
<td>usersDir</td>
<td>&lt;INSTANCE_DIR&gt;/workspace/app-server/users</td>
<td>zlux-app-server/deploy/instance/users</td>
<td></td>
</tr>
</tbody>
</table>
Application plug-in configuration

This topic describes application plug-ins that are defined in advance.

In the configuration file, you can specify a directory that contains JSON files, which tell the server what application plug-in to include and where to find it on disk. The backend of these application plug-ins use the server's plug-in structure, so much of the server-side references to application plug-ins use the term plug-in.

To include application plug-ins, define the location of the plug-ins directory in the configuration file, through the top-level attribute `pluginsDir`.

**Note:** In this example, the directory for these JSON files is the Application Server defaults. However, in an instance of Zowe it is best to provide a folder unique to that instance - usually `$INSTANCE_DIR/workspace/app-server/plugins`.

### Plug-ins directory example

```json
// All paths relative to zlux-app-server/lib
// In real installations, these values will be configured during the install process.
//...
"pluginsDir": "./defaults/plugins",
```

Logging configuration

For more information, see Logging utility on page 280.

ZSS configuration

Running ZSS requires a JSON configuration file that is similar or the same as the one used for the Zowe Application Server. The attributes that are needed for ZSS, at minimum, are: `productDir`, `siteDir`, `instanceDir`, `groupsDir`, `usersDir`, `pluginsDir` and `agent.http.port`. All of these attributes have the same meaning as described above for the server, but if the Zowe Application Server and ZSS are not run from the same location, then these directories can be different.

Attributes that control ZSS are in the agent object. For example, `agent.http.port` is the TCP port that ZSS will listen on to be contacted by the App Server. Define this in the configuration file as a value between 1024-65535. Similarly, if specified, `agent.http.ipAddresses` will be used to determine which IP addresses the server should bind to. Only the first value of the array is used. It can either be a hostname or an ipv4 address.

Example of the agent body:

```json
"agent": {
  "host": "localhost",
  "http": {
    "ipAddresses": ["127.0.0.1"],
    "port": 8542
  }
}
```

Connecting App Server to ZSS

When running the App Server, simply specify a few flags to declare which ZSS instance the App Server will proxy ZSS requests to:

- `-h`: Declares the host where ZSS can be found. Use as "-h <hostname>"
• \(-P\): Declares the port at which ZSS is listening. Use as \("-P \langle port\>\"

**Configuring ZSS for HTTPS**

To secure ZSS communication, you can use Application Transparent Transport Layer Security (AT-TLS) to enable Hyper Text Transfer Protocol Secure (HTTPS) communication with ZSS.

Before you begin, you must have a basic knowledge of your security product, e.g. RACF, and AT-TLS, and you must have Policy Agent configured. For more information on AT-TLS and Policy Agent, see the z/OS Knowledge Center.

You must have the authority to alter security definitions related to certificate management, and you must be authorized to work with and update the Policy Agent.

To configure HTTPS communication between ZSS and the Zowe App Server, you need a key ring which contains the ZSS server certificate and its Certificate Authority (CA) certificate. You can use an internal CA to create the ZSS server certificate, or you can buy the ZSS server certificate from a well-known commercial Certificate Authority. Next you define an AT-TLS rule which points to the key ring used by the ZSS server. Then you copy the CA certificate to the Zowe App Server key store and update the Zowe App Server configuration file.

**Note:** Bracketed values below (including the brackets) are variables. Replace them with values relevant to your organization. Always use the same value when substituting a variable that occurs multiple times.

**Creating certificates and key ring for the ZSS server using RACF**

In this step you will create a root CA certificate and a ZSS server certificate signed by the CA certificate. Next you create a key ring owned by the ZSS server with the certificates attached.

**Key variables:**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ca_common_name]</td>
<td></td>
</tr>
<tr>
<td>[ca_label]</td>
<td></td>
</tr>
<tr>
<td>[server_userid]</td>
<td></td>
</tr>
<tr>
<td>[server_common_name]</td>
<td></td>
</tr>
<tr>
<td>[server_label]</td>
<td></td>
</tr>
<tr>
<td>[ring_name]</td>
<td></td>
</tr>
<tr>
<td>[output_dataset_name]</td>
<td></td>
</tr>
</tbody>
</table>

**Note:**

- [server_userid] must be the ZSS server user ID.
- [server_common_name] must be the ZSS server host name.

1. Enter the following RACF command to generate a CA certificate:

```
RACDCERT CERTAUTH GENCERT +
  SUBJECTSDN(CN('[ca_common_name]') +
  OU('[organizational_unit]') +
  O('[organization_name]') +
  L('[locality]') SP('[state_or_province]') C('[country]') +
  KEYUSAGE(CERTSIGN) +
  WITHLABEL('[ca_label]') +
  NOTAFTER(DATE('[yyyy/mm/dd]')) +
  SIZE(2048)
```

1. Enter the follow RACF command to generate a server certificate signed by the CA certificate:

```
RACDCERT ID('[server_userid]') GENCERT +
  SUBJECTSDN(CN('[common_name]') +
  O('[organization_name]') +
  L('[locality]') SP('[state_or_province]') C('[country]') +
  KEYUSAGE(CERTSIGN) +
  WITHLABEL('[server_label]') +
  NOTAFTER(DATE('[yyyy/mm/dd]')) +
  SIZE(2048)
```
Enter the following RACF commands to create a key ring and connect the certificates to the key ring:

RACDCERT ID([server_userid]) ADDRING([ring_name])
RACDCERT ID([server_userid]) CONNECT(ID([server_userid]) +
   LABEL('[server_label]') RING([ring_name]) DEFAULT)
RACDCERT ID([server_userid]) CONNECT(CERTAUTH +
   LABEL('[ca_label]') RING([ring_name]))

Enter the following RACF command to refresh the DIGTRING and DIGTCERT classes to activate your changes:

SETROPTS RACLIST(DIGTRING,DIGTCERT) REFRESH

Enter the following RACF commands to verify your changes:

RACDCERT ID([server_userid]) LISTRING([ring_name])
RACDCERT ID([server_userid]) LISTCHAINLABEL('[server_label]')

Enter the following RACF commands to allow the ZSS server to use the certificates. Only issue the RDEFINE
commands if the profiles do not yet exist.

RDEFINE FACILITY IRR.DIGTCERT.LIST UACC(NONE)
RDEFINE FACILITY IRR.DIGTCERT.LISTRING UACC(NONE)
PERMIT IRR.DIGTCERT.LIST CLASS(FACILITY) ACCESS(READ) +
   ID([server_userid])
PERMIT IRR.DIGTCERT.LISTRING CLASS(FACILITY) ACCESS(READ) +
   ID([server_userid])
SETROPTS RACLIST(FACILITY) REFRESH

Note: These sample commands use the FACILTY class to manage certificate related authorizations. You can also use
the RDATALIB class, which offers granular control over the authorizations.

Enter the following RACF command to export the CA certificate to a dataset so it can be imported by the Zowe
App Server:

RACDCERT CERTAUTH EXPORT(LABEL('[ca_label]')) +
   DSN('[output_dataset_name]') FORMAT(CERTB64)

Defining the AT-TLS rule

To define the AT-TLS rule, use the sample below to specify values in your AT-TLS Policy Agent Configuration file:
Configuring the Zowe App Server for HTTPS communication with ZSS

Copy the CA certificate to the ZSS server. Then in the Zowe App Server configuration file, specify the location of the certificate, and add a parameter to specify that ZSS uses AT-TLS.

1. Enter the following command to copy the CA certificate to the correct location in UNIX System Services (USS):
   
   cp "//'[output_dataset_name]'" 'zlux-app-server/deploy/instance/ZLUX/serverConfig/[ca_cert]'

1. In the [INSTANCE_DIR]/workspace/app-server/serverConfig directory, open the server.json file.
2. In the node.https.certificateAuthorities object, add the CA certificate file path, for example:

   "certificateAuthorities": ["[INSTANCE_DIR]/workspace/app-server/serverConfig/[ca_cert]"]
1. In the `agent.http` object add the key-value pair "attls": true, for example:

```
"agent": {
    "host": "localhost",
    "http": {
        "ipAddresses": ["127.0.0.1"],
        "port": 8542,
        "attls": true
    }
}
```

### Installing additional ZSS instances

After you install Zowe, you can install and configure additional instances of ZSS on the same z/OS server. You might want to do this to test different ZSS versions.

The following steps assume you have installed a Zowe runtime instance (which includes ZSS), and that you are installing a second runtime instance to install an additional ZSS.

1. To stop the installed Zowe runtime, in SDSF enter the following command:

```
/C %(ZOWE_PREFIX)%(ZOWE_INSTANCE)SV
```

Where `ZOWE_PREFIX` and `ZOWE_INSTANCE` are specified in your configuration (and default to ZWE and 1)

2. Install a new Zowe runtime by following steps in Installing Zowe on z/OS.

   **Note:** In the `zowe-install.yaml` configuration file, specify ports that are not used by the first Zowe runtime.

3. To restart the first Zowe runtime, in SDSF enter the following command:

```
/S ZWESVSTC,SRVRPATH='$(ZOWE_ROOT_DIR)
```

Where `$(ZOWE_ROOT_DIR)` is the first Zowe runtime root directory. By default the command starts the most recently installed runtime unless you specify the root directory of the runtime that you want to start.

4. To specify a name for the new ZSS instance, follow these steps:

   a. Copy the PROCLIB member JCL named `ZWESISTC` that was installed with the new runtime.
   b. Rename the copy to uniquely identify it as the JCL that starts the new ZSS, for example `ZWESIS02`.
   c. Edit the JCL, and in the `NAME` parameter specify a unique name for the cross-memory server, for example:

```
//ZWESIS02  PROC NAME='ZWESIS_MYSRV',MEM=00,RGN=0M
```

   Where `ZWESIS_MYSRV` is the unique name of the new ZSS.

5. To start the new ZSS, in SDSF enter the following command:

```
/S ZWESIS02
```

6. Make sure that the TSO user ID that runs the first ZSS started task also runs the new ZSS started task. The default ID is `ZWESVUSR`.

7. In the new ZSS `server.json` configuration file, add a "privilegedServerName" parameter and specify the new ZSS name, for example:

```
"productDir": "../defaults",
// All paths relative to zlux-app-server/bin
// In real installations, these values will be configured during the install.
"productDir": "../defaults",
"siteDir": "../deploy/site",
"instanceDir": "../deploy/instance",
"groupsDir": "../deploy/instance/groups",
"usersDir": "../deploy/instance/users",
"pluginsDir": "../defaults/plugins",
```
"privilegedServerName":"ZWESIS_MYSRV",
"dataserviceAuthentication": { ... }

**Note:** The instance location of `server.json` is `$INSTANCE_DIR/workspace/app-server/
serverConfig/server.json`, and the defaults are stored in `$ROOT_DIR/components/app-server/
share/zlux-app-server/default/serverConfig/server.json`

8. To start the new Zowe runtime, in SDSF enter the following command:

```
/S ZWESVSTC,INSTANCE='$ZOWE_INSTANCE_DIR'
```

9. To verify that the new cross-memory server is being used, check for the following messages in the `ZWESVSTC`
server job log:

```
ZIS status - Ok (name='ZWESIS_MYSRV ', cmsRC=0, description='Ok',
clientVersion=2)
```

### Controlling access to applications

You can control which applications are accessible (visible) to all Zowe desktop users, and which are accessible only
to individual users. For example, you can make an application that is under development only visible to the team
working on it.

You control access by editing JSON files that list the apps. One file lists the apps all users can see, and you can create
a file for each user. When a user logs into the desktop, Zowe determines the apps that user can see by concatenating
their list with the all users list.

You can also control access to the JSON files. The files are accessible directly on the file system, and since they are
within the configuration dataservice directories, they are also accessible via REST API. We recommend that only
Zowe administrators be allowed to access the file system locations, and you control that by setting the directories
and their contents to have file permissions on z/OS that only allow the Zowe admin group read & write access. You
control who can read and edit the JSON files through the REST API by controlling who can [Creating authorization
profiles on page 131](#)

### Controlling application access for all users

1. Open the Zowe Application Server configuration JSON file. By default, the file is in the following location:

```
$ROOT_DIR/components/app-server/share/zlux-app-server/defaults/
serverConfig/server.json
```

2. To enable RBAC, in the `dataserviceAuthentication` object add the object: "rbac": true

3. Navigate to the following location:

```
$ROOT_DIR/components/app-server/share/zlux-app-server/defaults/ZLUX/
pluginStorage/org.zowe.zlux.bootstrap/plugins
```

4. Copy the `allowedPlugins.json` file and paste it in the following location:

```
.zowe/workspace/app-server/ZLUX/pluginStorage/org.zowe.zlux.bootstrap
```

5. Open the copied `allowedPlugins.json` file and perform either of the following steps:

- To an application unavailable, delete it from the list of objects.
- To make an application available, copy an existing plugin object and specify the application's values in the
  new object. Identifier and version attributes are required.

6. [Stopping the ZWESVSTC PROC on page 113](#).
Controlling application access for individual users

1. Open the Zowe Application Server configuration JSON file. By default, the file is in the following location:

\$ROOT_DIR/components/app-server/share/zlux-app-server/defaults/serverConfig/server.json

2. To enable RBAC, in the dataserviceAuthentication object add the object: "rbac": true

3. In the user's ID directory path, in the /pluginStorage directory, create /org.zowe.zlux.bootstrap
   \plugins directories. For example:

   .zowe\workspace\app-server\users\TS6320\ZLUX\pluginStorage
   \org.zowe.zlux.bootstrap\plugins

4. In the /plugins directory, create an allowedPlugins.json file. You can use the default
   allowedPlugins.json file as a template by copying it from the following location:

   \$ROOT_DIR/components/app-server/share/zlux-app-server/defaults/ZLUX/
   pluginStorage/org.zowe.zlux.bootstrap/plugins

5. Open the allowedPlugins.json file and specify applications that user can access. For example:

   {
   "allowedPlugins": [
   {
   "identifier": "org.zowe.appA",
   "versions": ["*"]
   },
   {
   "identifier": "org.zowe.appB",
   "versions": ["*"]
   }
   ]
   }

Notes:
- Identifier and version attributes are required.
- When a user logs in to the desktop, Zowe determines which apps they can see by concatenating the list of apps
  available to all users with the apps available to the individual user.

Controlling access to dataservices

To apply role-based access control (RBAC) to dataservice endpoints, you must enable RBAC for Zowe, and then use
a z/OS security product such as RACF to map roles and authorities to the endpoints. After you apply RBAC, Zowe
checks authorities before allowing access to the endpoints.

You can apply access control to Zowe endpoints and to your application endpoints. Zowe provides endpoints for a
set of configuration dataservices and a set of core dataservices. Applications can use Configuration Dataservice on
page 266 to store and their own configuration and other data. Administrators can use core endpoints to get status
information from the Application Framework and ZSS servers. Any dataservice added as part of an application plugin
is a service dataservice.

Defining the RACF ZOWE class

If you use RACF security, take the following steps define the ZOWE class to the CDT class:

1. Make sure that the CDT class is active and RACLISTed.
2. In TSO, issue the following command:

```plaintext
RDEFINE CDT ZOWE UACC(NONE)
CDTINFO(
  DEFAULTUACC(NONE)
  FIRST(ALPHA) OTHER(ALPHA,NATIONAL,NUMERIC,SPECIAL)
  MAXLENGTH(246)
  POSIT(607)
  RACLIST(DISALLOWED))
```

If you receive the following message, ignore it:

"Warning: The POSIT value is not within the recommended ranges for installation use. The valid ranges are 19-56 and 128-527."

3. In TSO, issue the following command to refresh the CDT class:

```plaintext
SETROPTS RACLIST(CDT) REFRESH
```

4. In TSO, issue the following command to activate the ZOWE class:

```plaintext
SETROPTS CLASSACT(ZOWE)
```

For more information RACF security administration, see the IBM Knowledge Center at https://www.ibm.com/support/knowledgecenter/.

### Enabling RBAC

By default, RBAC is disabled and all authenticated Zowe users can access all dataservices. To enable RBAC, follow these steps:

1. Open the Zowe Application Server configuration JSON file. In the a server instance, the configuration file is `$INSTANCE_DIR/workspace/app-server/serverConfig/server.json`.
2. In the `dataserviceAuthentication` object, add "rbac": true.

### Creating authorization profiles

For users to access endpoints after you enable RBAC, in the ZOWE class you must create System Authorization Facility (SAF) profiles for each endpoint and give users READ access to those profiles.

Endpoints are identified by URIs in the following format:

```
/<product>/plugins/<plugin_id>/services/<service>/<version>/<path>
```

For example:

```
/ZLUX/plugins/org.zowe.foo/services/baz/_current/users/fred
```

Where the path is /users/fred.

SAF profiles have the following format:

```
<product>.<instance_id>.<service>.<pluginid_with_underscores>.<service>.<HTTP_method>.<url_with_forward_slashes_replaced_by_periods>
```

For example, to issue a POST request to the dataservice endpoint documented above, users must have READ access to the following profile:

```
ZLUX.DEFAULT.SVC.ORG_ZOWE_FOO.BAZ.POST.USERS.FRED
```

For configuration dataservice endpoint profiles use the service code CFG. For core dataservice endpoints use COR. For all other dataservice endpoints use SVC.
Creating generic authorization profiles

Some endpoints can generate an unlimited number of URIs. For example, an endpoint that performs a DELETE action on any file would generate a different URI for each file, and users can create an unlimited number of files. To apply RBAC to this type of endpoint you must create a generic profile, for example:

ZLUX.DEFAULT.COR.ORG_ZOWE_FOO.BAZ.DELETE.**

You can create generic profile names using wildcards, such as asterisks (*). For information on generic profile naming, see IBM documentation.

Configuring basic authorization

The following are recommended for basic authorization:

- To give administrators access to everything in Zowe, create the following profile and give them UPDATE access to it: ZLUX.**
- To give non-administrators basic access to the site and product, create the following profile and give them READ access to it: ZLUX.*.ORG_ZOWE_*
- To prevent non-administrators from configuring endpoints at the product and instance levels, create the following profile and do not give them access to it: ZLUX.DEFAULT.CFG.**
- To give non-administrators all access to user, create the following profile and give them UPDATE access to it: ZLUX.DEFAULT.CFG.*.*.USER.**

Endpoint URL length limitations

SAF profiles cannot contain more than 246 characters. If the path section of an endpoint URL is long enough that the profile name exceeds the limit, the path is trimmed to only include elements that do not exceed the limit. To avoid this issue, we recommend that application developers maintain relatively short endpoint URL paths.

For information on endpoint URLs, see Dataservice endpoint URL lengths and RBAC

Multi-factor authentication configuration

Multi-factor authentication is an optional feature for Zowe.

As of Zowe version 1.8.0, the Zowe App Framework, Desktop, and all apps present in the SMP/E or convenience builds support out-of-band MFA by entering an MFA assigned token or passcode into password field of the Desktop login screen, or by accessing the app-server /auth REST API endpoint.

For a list of compatible MFA products, see Known compatible MFA products

Session duration and expiration

After successful authentication, a Zowe Desktop session is created by authentication plugins.

The duration of the session is determined by the plugin used. Some plugins are capable of renewing the session prior to expiration, while others may have a fixed session length.

Zowe is bundled with a few of these plugins:

- **apiml-auth**: Calls the Zowe API Mediation Layer from the app-server for authentication. By default, the Mediation Layer calls z/OSMF to answer the authentication request. The session created mirrors the z/OSMF session.
- **zosmf-auth**: Calls z/OSMF auth from the app-server to answer the authentication request. The created z/OSMF session is valid for about 8 hours.
- **zss-auth**: Calls Zowe ZSS from the app-server to answer the authentication request. The created ZSS session is valid for 1 hour, but is renewable on request prior to expiration. In the Desktop, the session is automatically renewed if the user is detected as active. If the user is detected as idle, the session will expire.

When a session expires, the credentials used for the initial login are likely to be invalid for re-use, since MFA credentials are often one-time-use or time-based.

In the Desktop, Apps that you opened prior to expiration will remain open so that your work can resume after entering new credentials.
**Configuration**

When you use the default Zowe SMP/E or convenience build configuration, you do not need to change Zowe to get started with MFA.

To configure Zowe for MFA with a configuration other than the default, take the following steps:

1. Choose an App Server security plugin that is compatible with MFA. The **Session duration and expiration** on page 132 plugins are all compatible.
2. Locate the App Server's configuration file in `$INSTANCE_DIR/workspace/app-server/serverConfig/server.json`
3. Edit the configuration file to modify the section `dataserviceAuthentication`.
4. Set `defaultAuthentication` to the same category as the plugin of choice, for example:
   - `apiml-auth`: "apiml"
   - `zosmf-auth`: "zosmf"
   - `zss-auth`: "zss"
5. Define the plugins to use in the configuration file by adding a section for the chosen category within `dataserviceAuthentication.implementationDefaults` as an object with the attribute `plugins`, which is an array of plugin ID strings, where the plugins each have the following IDs:
   - `apiml-auth`: "org.zowe.zlux.auth.apiml"
   - `zosmf-auth`: "org.zowe.zlux.auth.zosmf"
   - `zss-auth`: "org.zowe.zlux.auth.zss"

The following is an example configuration for `zss-auth`, as seen in a default installation of Zowe:

```json
"dataserviceAuthentication": {
  "defaultAuthentication": "zss",
  "implementationDefaults": {
    "zss": {
      "plugins": [
        "org.zowe.zlux.auth.zss"
      ]
    }
  }
}
```

**Enabling tracing**

To obtain more information about how a server is working, you can enable tracing within the `server.json` file. For example:

```json
"logLevels": {
  "_zsf.routing": 0,
  "_zsf.install": 0,
  "_zss.traceLevel": 0,
  "_zss.fileTrace": 1
}
```

Specify the following settings inside the `logLevels` object.

All settings are optional.

**Zowe Application Server tracing**

To determine how the Zowe Application Server (`zlux-app-server`) is working, you can assign a logging level to one or more of the pre-defined logger names in the `server.json` file.

The log prefix for the Zowe Application Server is `_zsf`, which is used by the server framework. (Applications and plug-ins that are attached to the server do not use the `_zsf` prefix.)
The following are the logger names that you can specify:

_**zsf.bootstrap**_ Logging that pertains to the startup of the server.

_**zsf.auth**_ Logging for network calls that must be checked for authentication and authorization purposes.

_**zsf.static**_ Logging of the serving of static files (such as images) from an application’s /web folder.

_**zsf.child**_ Logging of child processes, if any.

_**zsf.utils**_ Logging for miscellaneous utilities that the server relies upon.

_**zsf.proxy**_ Logging for proxies that are set up in the server.

_**zsf.install**_ Logging for the installation of plug-ins.

_**zsf.apiml**_ Logging for communication with the api mediation layer.

_**zsf.routing**_ Logging for dispatching network requests to plug-in dataservices.

_**zsf.network**_ Logging for the HTTPS server status (connection, ports, IP, and so on)

**Log levels**

The log levels are:

- **SEVERE** = 0,
- **WARNING** = 1,
- **INFO** = 2,
- **FINE** = 3,
- **FINER** = 4,
- **FINEST** = 5

FINE, FINER, and FINEST are log levels for debugging, with increasing verbosity.

**Enabling tracing for ZSS**

To increase logging for ZSS, you can assign a logging level (an integer value greater than zero) to one or more of the pre-defined logger names in the `server.json` file.

A higher value specifies greater verbosity.

The log prefix for ZSS is _**zss**_. The following are the logger names that you can specify:

**_zss.traceLevel:_** Controls general server logging verbosity.

**_zss.fileTrace:_** Logs file serving behavior (if file serving is enabled).

**_zss.socketTrace:_** Logs general TCP Socket behavior.

**_zss.httpParseTrace:_** Logs parsing of HTTP messages.

**_zss.httpDispatchTrace:_** Logs dispatching of HTTP messages to dataservices.

**_zss.httpHeadersTrace:_** Logs parsing and setting of HTTP headers.

**_zss.httpSocketTrace:_** Logs TCP socket behavior for HTTP.

**_zss.httpCloseConversationTrace:_** Logs HTTP behavior for when an HTTP conversation ends.

**_zss.httpAuthTrace:_** Logs behavior for session security.

When you are finished specifying the settings, save the `server.json` file.

**Zowe Application Framework logging**

The Zowe Application Framework log files contain processing messages and statistics. The log files are generated in the following default locations:

- **Zowe Application Server:** `$INSTANCE_DIR/logs/appServer-yyyy-mm-dd-hh-mm.log`
- **ZSS**: `$INSTANCE_DIR/logs/zssServer-yyyy-mm-dd-hh-mm.log`

The logs are timestamped in the format `yyyy-mm-dd-hh-mm` and older logs are deleted when a new log is created at server startup.

### Controlling the logging location

The log information is written to a file and to the screen. (On Windows, logs are written to a file only.)

**ZLUX_NODE_LOG_DIR and ZSS_LOG_DIR environment variables**

To control where the information is logged, use the environment variable `ZLUX_NODE_LOG_DIR`, for the Zowe Application Server, and `ZSS_LOG_DIR`, for ZSS. While these variables are intended to specify a directory, if you specify a location that is a file name, Zowe will write the logs to the specified file instead (for example: `/dev/null` to disable logging).

When you specify the environment variables `ZLUX_NODE_LOG_DIR` and `ZSS_LOG_DIR` and you specify directories rather than files, Zowe will timestamp the logs and delete the older logs that exceed the `ZLUX_NODE_LOGS_TO_KEEP` threshold.

**ZLUX_NODE_LOG_FILE and ZSS_LOG_FILE environment variables**

If you set the log file name for the Zowe Application Server by setting the `ZLUX_NODE_LOG_FILE` environment variable, or if you set the log file for ZSS by setting the `ZSS_LOG_FILE` environment variable, there will only be one log file, and it will be overwritten each time the server is launched.

**Note:** When you set the `ZLUX_NODE_LOG_FILE` or `ZSS_LOG_FILE` environment variables, Zowe will not override the log names, set a timestamp, or delete the logs.

If the directory or file cannot be created, the server will run (but it might not perform logging properly).

### Retaining logs

By default, the last five logs are retained. To specify a different number of logs to retain, set `ZLUX_NODE_LOGS_TO_KEEP` (Zowe Application Server logs) or `ZSS_LOGS_TO_KEEP` (ZSS logs) to the number of logs that you want to keep. For example, if you set `ZLUX_NODE_LOGS_TO_KEEP` to 10, when the eleventh log is created, the first log is deleted.

### Administering the servers and plugins using an API

You can use a REST API to retrieve and edit Zowe Application Server and ZSS server configuration values, and list, add, update, and delete plugins. If an administrator has configured Zowe to use RBAC, they must authorize you to access the endpoints.

The API returns the following information in a JSON response:

<table>
<thead>
<tr>
<th>API</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/server (GET)</td>
<td>Returns a list of accessible server endpoints for the Zowe Application Server.</td>
</tr>
<tr>
<td>/server/config (GET)</td>
<td>Returns the Zowe Application Server configuration from the <code>zluxserver.json</code> file.</td>
</tr>
<tr>
<td>/server/log (GET)</td>
<td>Returns the contents of the Zowe Application Server log file.</td>
</tr>
<tr>
<td>/server/loglevels (GET)</td>
<td>Returns the verbosity levels set in the Zowe Application Server logger.</td>
</tr>
<tr>
<td>/server/environment (GET)</td>
<td>Returns Zowe Application Server environment information, such as the operating system version, node server version, and process ID.</td>
</tr>
<tr>
<td>/server/reload (GET)</td>
<td>Reloads the Zowe Application Server. Only available in cluster mode.</td>
</tr>
</tbody>
</table>
### API Description

<table>
<thead>
<tr>
<th>API</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/server/agent (GET)</td>
<td>Returns a list of accessible server endpoints for the ZSS server.</td>
</tr>
<tr>
<td>/server/agent/config (GET)</td>
<td>Returns the ZSS server configuration from the zluxserver.json file.</td>
</tr>
<tr>
<td>/server/agent/log (GET)</td>
<td>Returns the contents of the ZSS log file.</td>
</tr>
<tr>
<td>/server/agent/loglevels (GET)</td>
<td>Returns the verbosity levels of the ZSS logger.</td>
</tr>
<tr>
<td>/server/agent/environment (GET)</td>
<td>Returns ZSS environment information.</td>
</tr>
<tr>
<td>/server/config/:attrib (POST)</td>
<td>Specify values for server configuration attributes in the zluxserver.json file. You can change a subset of configuration values.</td>
</tr>
<tr>
<td>/server/logLevels/name/:componentName/level/:level (POST)</td>
<td>Specify the logger that you are using and a verbosity level.</td>
</tr>
<tr>
<td>/plugins (GET)</td>
<td>Returns a list of all plugins and their dataservices.</td>
</tr>
<tr>
<td>/plugins (PUT)</td>
<td>Adds a new plugin or upgrades an existing plugin. Only available in cluster mode.</td>
</tr>
<tr>
<td>/plugins/:id (DELETE)</td>
<td>Deletes a plugin. Only available in cluster mode.</td>
</tr>
</tbody>
</table>

Swagger API documentation is provided in the $ROOT_DIR/components/app-server/share/zlux-app-server/doc/swagger/server-plugins-api.yaml file. To see it in HTML format, you can paste the contents into the Swagger editor at https://editor.swagger.io/.

**Note:** The "agent" end points interact with the agent specified in the server.json file. By default this is ZSS.

## Configuring Zowe CLI

This section explains how to define and verify your connection to the mainframe through Zowe™ CLI. You can also configure CLI settings, such as the level of detail produced in logs and the location of the home directory on your computer.

**Note:** The configuration for the CLI is stored on your computer in a directory such as C:\Users\user01\.zowe. The configuration includes log files, your profile information, and CLI plug-ins that are installed. When you troubleshoot an issue with the CLI, the log files in the imperative and zowe folders contain valuable information.

- Defining Zowe CLI connection details on page 136
- Testing Zowe CLI connection to z/OSMF
- Setting Zowe CLI log levels on page 141
- Setting the Zowe CLI home directory on page 142

### Defining Zowe CLI connection details

Zowe CLI has a command option order of precedence that lets you define arguments and options for commands in multiple ways (command-line, environment variables, and profiles). This provides flexibility when you issue commands and write automation scripts. This topic explains order of precedence and different methods for specifying your mainframe connection details.

- Understanding command option order of precedence on page 137
- Creating Zowe CLI profiles on page 137
- Defining Environment Variables on page 138
- Integrating with API Mediation Layer on page 139
Understanding command option order of precedence

Before you issue commands, it is helpful to understand the command option order of precedence. The following is the order in which Zowe CLI searches for your command arguments and options when you issue a command:

1. Arguments and options that you specify directly on the command line.
2. Environment variables that you define in the computer's operating system. For more information, see Defining Environment Variables on page 138
3. User profiles that you create.
4. The default value for the argument or option.

The affect of the order is that if you omit an argument/option from the command line, Zowe CLI searches for an environment variable that contains a value that you defined for the argument/option. If Zowe CLI does not find a value for the argument/option in an environment variable, Zowe CLI searches your user profiles for the value that you defined for the option/argument. If Zowe CLI does not find a value for the argument/option in your profiles, Zowe CLI executes the command using the default value for the argument/option.

Note: If a required option or argument value is not located, you receive a syntax error message that states Missing Positional Argument or Missing Option.

Creating Zowe CLI profiles

Profiles let you store configuration details for use on multiple commands. You can create a profile that contains your username, password, and connection details for a particular mainframe system, then reuse that profile to avoid typing it again on every command. Switch between profiles to quickly target different mainframe subsystems.

Notes:

• Profile values are stored on your computer in plaintext in the C:\Users\<yourUsername>\.zowe \profiles folder.
• Profiles are not required to use the CLI. You can choose to specify all connection details in options on every command.
• For information about securely connecting to the server when you issue commands, see Certificate security on page 141.

Displaying profiles help

To learn about the options available for creating zosmf profiles, issue the following command:

```
zowe profiles create zosmf-profile --help
```

Creating and Using a profile

Create a profile, then use the profile when you issue a command. For example, substitute your connection details and issue the following command to create a profile with the name myprofile123:

```
zowe profiles create zosmf-profile myprofile123 --host host123 --port port123 --user ibmuser --password pass123
```

Issue the following command to list all data sets under the username ibmuser on the system specified in myprofile123:

```
zowe zos-files list data-set "ibmuser.*" --zosmf-profile myprofile123
```

After you create a profile, you can verify that it can communicate with z/OSMF. For more information, see Testing Connection to z/OSMF.

Creating a profile that accesses API Mediation Layer

You can create profiles that access either an exposed API or API Mediation Layer (API ML) in the following ways:

• When you create a profile, specify the host and port of the API that you want to access. When you only provide the host and port configuration, Zowe CLI connects to the exposed endpoints of a specific API.
• When you create a profile, specify the host, port, and the base path of API ML instance that you want to access. Using the base path to API ML, Zowe CLI routes your requests to an appropriate instance of the API based on the system load and the available instances of the API.

For more information, see Integrating with API Mediation Layer on page 139.

Example:
The following example illustrates the command to create a profile that connects to z/OSMF through API ML with the base path my/api/layer:

```
zowe profiles create zosmf myprofile -H <myhost> -P <myport> -u <myuser> --pw <mypass> --base-path <my/api/layer>
```

After you create a profile, verify that it can communicate with z/OSMF. For more information, see Testing Zowe CLI connection to z/OSMF.

Defining Environment Variables
You can define environment variables in your environment to execute commands more efficiently. You can store a value, such as your password, in an environment variable, then issue commands without specifying your password every time. The term environment refers to your operating system, but it can also refer to an automation server, such as Jenkins or a Docker container. In this section we explain how to transform arguments and options from Zowe CLI commands into environment variables and define them with a value.

• Assigning an environment variable for a value that is commonly used.
  For example, you might want to specify your mainframe user name as an environment variable on your computer. When you issue a command and omit the `--username` argument, Zowe CLI automatically uses the value that you defined in the environment variable. You can now issue a command or create any profile type without specifying your user name repeatedly.

• Overriding a value that is used in existing profiles.
  For example, you might want to override a value that you previously set on multiple profiles to avoid recreating each profile. This reduces the number of profiles that you need to maintain and lets you avoid specifying every option on command line for one-off commands.

• Specifying environment variables in a Jenkins environment (or other automation server) to store credentials securely.
  You can set values in Jenkins environment variables for use in scripts that run in your CI/CD pipeline. You can define Jenkins environment variables in the same manner that you can on your computer. You can also define sensitive information in the Jenkins secure credential store. For example, you might need to define your mainframe password in the secure credential store so that it is not available in plain text.

Transforming arguments/options to environment variable format
Transform the option/argument into the correct format for a Zowe CLI environment variable, then define values to the new variable. The following rules apply to this transformation:

• Prefix environment variables with ZOWE_OPT_
• Convert lowercase letters in arguments/options to uppercase letters
• Convert hyphens in arguments/options to underscores

Tip: See your operating system documentation for information about how to set and get environment variables. The procedure for setting environment variables varies between Windows, Mac, and various versions of Linux operating systems.

Examples:
The following table shows command line options that you might want to transform and the resulting environment variable to which you should define the value. Use the appropriate procedure for for your operating system to define the variables.
<table>
<thead>
<tr>
<th>Command Option</th>
<th>Environment Variable</th>
<th>Use Case</th>
</tr>
</thead>
<tbody>
<tr>
<td>--user</td>
<td>ZOWE_OPT_USER</td>
<td>Define your mainframe user name to an environment variable to avoid specifying it on all commands or profiles.</td>
</tr>
<tr>
<td>--reject-unauthorized</td>
<td>ZOWE_OPT_REJECT_UNAUTHORIZED</td>
<td>Define a value of true to the --reject-unauthorized flag when you always require the flag and do not want to specify it on all commands or profiles.</td>
</tr>
</tbody>
</table>

Setting environment variables in an automation server

You can use environment variables in an automation server, such as Jenkins, to write more efficient scripts and make use of secure credential storage.

You can either set environment variables using the `SET` command within your scripts, or navigate to Manage Jenkins \> Configure System \> Global Properties and define an environment variable in the Jenkins GUI. For example:

```
<table>
<thead>
<tr>
<th>Global properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>☑ Disable deferred wipeout on this node</td>
</tr>
<tr>
<td>☑ Environment variables</td>
</tr>
<tr>
<td>☑ List of variables</td>
</tr>
<tr>
<td>Name</td>
</tr>
<tr>
<td>TEST_VARIABLE</td>
</tr>
<tr>
<td>Value</td>
</tr>
<tr>
<td>test-value</td>
</tr>
</tbody>
</table>
```

Using secure credential storage

Automation tools such as Jenkins automation server usually provide a mechanism for securely storing configuration (for example, credentials). In Jenkins, you can use `withCredentials` to expose credentials as an environment variable (ENV) or Groovy variable.

Note: For more information about using this feature in Jenkins, see Credentials Binding Plugin in the Jenkins documentation.

Integrating with API Mediation Layer

The API Mediation Layer provides a single point of access to a defined set of microservices. The API Mediation Layer provides cloud-like features such as high-availability, scalability, dynamic API discovery, consistent security, a single sign-on experience, and API documentation.

When Zowe CLI executes commands that connect to a service through the API Mediation Layer, the layer routes the command execution requests to an appropriate instance of the API. The routing path is based on the system load and available instances of the API.

Use the `--base-path` option on commands to let all of your Zowe CLI core command groups (excludes plug-in groups) access REST APIs through an API Mediation Layer. To access API Mediation Layers, you specify the base path, or URL, to the API gateway as you execute your commands. Optionally, you can define the base path URL as an environment variable or in a profile that you create.
Examples:
The following example illustrates the base path for a REST request that is not connecting through an API Mediation Layer to one system where an instance of z/OSMF is running:

```
https://mymainframehost:port/zosmf/restjobs/jobs
```

The following example illustrates the base path (named api/v1/zosmf1) for a REST request to an API mediation layer:

```
https://myapilayerhost:port/api/v1/zosmf1/zosmf/restjobs/jobs
```

The following example illustrates the command to verify that you can connect to z/OSMF through an API Mediation Layer that contains the base path my/api/layer:

```
zowe zosmf check status -H <myhost> -P <myport> -u <myuser> --pw <mypass> --base-path <my/api/layer>
```

More Information:

- Zowe overview on page 8
- Creating a profile that accesses API Mediation Layer on page 137

Testing Zowe CLI connection to z/OSMF

You can issue a command at any time to receive diagnostic information from the server and confirm that Zowe CLI can communicate with z/OSMF or other mainframe APIs.

**Important!** By default, the server certificate is verified against a list of Certificate Authorities (CAs) trusted by Mozilla. This handshake ensures that the CLI can trust the server. You can append the flag `--ru false` to any of the following commands to bypass the certificate verification against CAs. If you use the `--ru false` flag, ensure that you understand the potential security risks of bypassing the certificate requirement at your site. For the most secure environment, system administrators configure a server keyring with a server certificate signed by a Certificate Authority (CA). For more information, see Certificate security on page 141.

**Without a Profile**

Verify that your CLI instance can communicate with z/OSMF.

```
zowe zosmf check status --host <host> --port <port> --user <username> --pass <password>
```

**Default profile**

After you Creating Zowe CLI profiles on page 137, verify that you can use your default profile to communicate with z/OSMF:

```
zowe zosmf check status
```

**Specific profile**

After you Creating Zowe CLI profiles on page 137, verify that you can use a specific profile to communicate with z/OSMF:

```
zowe zosmf check status --zosmf-profile <profile_name>
```

The commands return a success or failure message and display information about your z/OSMF server, such as the z/OSMF version number. Report any failure to your systems administrator and use the information for diagnostic purposes.
Certificate security

Certificates authorize communication between a server and client, such as z/OSMF and Zowe CLI. The client CLI must "trust" the server to successfully issue commands. Use one of the following methods to let the CLI communicate with the server:

- Configure certificates signed by a Certificate Authority (CA) on page 141
- Extend trusted certificates on client on page 141
- Bypass certificate requirement with CLI flag on page 141

Configure certificates signed by a Certificate Authority (CA)

System Administrators can configure the server with a certificate signed by a Certificate Authority (CA) trusted by Mozilla. When a CA trusted by Mozilla exists in the certificate chain, the CLI automatically recognizes the server and authorizes the connection.

Related information:
- Using certificates with z/OS client/server applications in the IBM Knowledge Center.
- Configuring the z/OSMF key ring and certificate in the IBM Knowledge Center.
- Certificate management in Zowe API Mediation Layer
- Mozilla Included CA Certificate List

Extend trusted certificates on client

If your organization uses self-signed certificates in the certificate chain (rather than a CA trusted by Mozilla), you can download the certificate to your computer add it to the local list of trusted certificates. Provide the certificate locally using the NODE_EXTRA_CERTS environment variable. Organizations might want to configure all client computers to trust the self-signed certificate.

This blog post outlines the process for using environment variables to trust the self-signed certificate.

Bypass certificate requirement with CLI flag

If you do not have server certificates configured at your site, or you want to trust a known self-signed certificate, you can append the --reject-unauthorized false flag to your CLI commands. Setting the --reject-unauthorized flag to false rejects self-signed certificates and essentially bypasses the certificate requirement.

Important! Understand the security implications of accepting self-signed certificates at your site before you use this command.

Example:

```bash
zowe zosmf check status --host <host> --port <port> --user <username> --pass <password> --reject-unauthorized false
```

Setting Zowe CLI log levels

You can set the log level to adjust the level of detail that is written to log files:

Important! Setting the log level to TRACE or ALL might result in "sensitive" data being logged. For example, command line arguments will be logged when TRACE is set.

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Description</th>
<th>Values</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZOWE_APP_LOG_LEVEL</td>
<td>Zowe CLI logging level</td>
<td>Log4JS log levels (OFF, TRACE, DEBUG, INFO, WARN, ERROR, FATAL)</td>
<td>DEBUG</td>
</tr>
<tr>
<td>ZOWE_IMPERATIVE_LOG_LEVEL</td>
<td>Imperative CLI Framework logging level</td>
<td>Log4JS log levels (OFF, TRACE, DEBUG, INFO, WARN, ERROR, FATAL)</td>
<td>DEBUG</td>
</tr>
</tbody>
</table>
Setting the Zowe CLI home directory

You can set the location on your computer where Zowe CLI creates the .zowe directory, which contains log files, profiles, and plug-ins for the product:

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Description</th>
<th>Values</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZOWE_CLI_HOME</td>
<td>Zowe CLI home directory</td>
<td>Any valid path on your computer</td>
<td>Your computer default home directory</td>
</tr>
</tbody>
</table>

Using Zowe

Getting started tutorial

  - Give feedback on page 160

Learning objectives

This tutorial walks you through the Zowe™ interfaces, including the Zowe Desktop and Zowe CLI, with several simple tasks to help you get familiar with Zowe.

- If you are new to Zowe, start with this tutorial to explore the base Zowe features and functions.
- If you are already familiar with Zowe interfaces and capabilities, you might want to visit the Extending section which guides you to extend Zowe by creating your own APIs or applications.
  - Onboarding Overview on page 211
  - Overview on page 242
  - Developing for Zowe CLI on page 197

By the end of the session, you'll know how to:

- Log in to the Zowe Desktop
- Query jobs with filters and view the related status by using the JES Explorer
- View jobs by using the 3270 Terminal in the Zowe Desktop
- View and edit data sets by using the MVS Explorer
- Edit a data set and upload it to the mainframe by using Zowe Command-Line Interface (CLI)

As an introductory scenario, no previous knowledge of Zowe is needed.

Estimated time

This tutorial guides you through the steps in roughly 20 minutes. If you explore other concepts related to this tutorial, it can take longer to complete.
Prerequisites and assumptions

Before you begin, it is assumed that you have already successfully installed Zowe. You are ready to launch Zowe Desktop and Zowe CLI.

For information about how to install Zowe, see Introduction on page 48.

Important!

- In this tutorial, the following parameters are used as an example. Replace them with your own settings when you follow the tutorial in your environment.
  - URL to access the Zowe Desktop: https://s0w1:8544/ZLUX/plugins/org.zowe.zlux.bootstrap/web/index.html
  - Mainframe credentials:
    - Username: ibmuser
    - Password: sys1
  - It is assumed that you perform the tasks in a Windows environment and that you have Visual Studio Code (VS Code) installed.

Logging in to the Zowe Desktop

Access and navigate the Zowe Desktop to view the Zowe applications. In this tutorial, you will use the Firefox browser to log in to the Zowe Desktop.

The URL to access the Zowe Desktop is https://myhost:httpsPort/ZLUX/plugins/org.zowe.zlux.bootstrap/web/index.html in your own environment, where:

- myHost is the host on which you are running the Zowe Application Server.
- httpsPort is the value that was assigned to node.https.port in zluxserver.json. For example, if you run the Zowe Application Server on host myhost and the value that is assigned to node.https.port in zluxserver.json is 12345, you would specify https://myhost:12345/ZLUX/plugins/org.zowe.zlux.bootstrap/web/index.html.

Follow these steps:
1. In the address field, enter the URL to access the Zowe Desktop. In this tutorial, the following URL is used as an example:

https://s0wl:8544/2LUX/plugins/org.zowe.zlux.bootstrap/web/index.html

2. On the login page of the Zowe Desktop, enter your mainframe credentials. In this tutorial, the following ID is used as an example:

   • Username: ibmuser
   • Password: sys1

3. Press Enter.

Upon authentication of your user name and password, the Zowe Desktop opens. Several applications are pinned to the taskbar. Click the Start menu to see a list of applications that are installed by default. You can pin other applications to the taskbar by right-clicking the application icon and selecting Pin to taskbar.
Next, you will use the JES Explorer application to query the jobs with filters and view the related status.

**Querying JES jobs and viewing related status in JES Explorer**

Use the Job Entry Subsystem (JES) Explorer to query JES jobs with filters and view the related status.

**Follow these steps:**

1. Click the Start menu in the Zowe Desktop.

2. Scroll down to find the JES Explorer icon and click to open it. The JES Explorer is displayed. If prompted to provide credentials for authentication, enter your mainframe credentials.
3. Click the **Job Filters** column to expand the filter criteria. You can filter jobs on various criteria by Owner, Prefix, Job ID, and Status. By default, the jobs are filtered by Owner. In this tutorial, the example owner is **IBMUSER**.

4. To query the jobs starting with **SDSF** and in an active status, clear the field of **Owner**, then enter **SDSF* in the Prefix field and select **ACTIVE** from the **Status** drop-down list, and click **APPLY**.

**Note:** Wildcard is supported. Valid wildcard characters are asterisk (*), percent sign (%), and question mark (?).
5. From the job filter results, click the job named SDSF. The data sets for this job are listed.

6. Click JESJCL to open the JESJCL data set. The contents of this data set are displayed. You can also select other data sets to view their contents.

   **Tip:** You can hover over the text in purple color to display a hover help window.

You used the JES Explorer to query the JES jobs with filters and viewed the related steps, files, and status.

Close the JES Explorer window. Next, you'll use the TN3270 application plug-in in the Zowe Desktop to view the same job that you viewed in this task.

**Using the 3270 Terminal in the Zowe Desktop to view the job**

Use the 3270 Terminal application plug-in to view the same job that you filtered out in the previous task.

Zowe not only provides new, modern applications to interact with z/OS®, but it also integrates the traditional 3270 terminal interface that you may also be familiar with. The 3270 Terminal application plug-in provides a basic, emulated 3270 terminal connection to the mainframe via the Zowe Application Server.

**Follow these steps:**
1. From the taskbar at the bottom of the Zowe Desktop, click the 3270 Terminal icon to open the 3270 Terminal application plug-in.

The 3270 Terminal panel is displayed, which offers selections to access various mainframe services.
2. Enter the following command and press Enter to log on to TSO:

```
LOGON ibmuser
```
3. On the TSO/E LOGON panel, enter the password `sys1` in the **Password** field and press Enter.

You successfully log on to TSO.
4. When you see the following screen, press Enter. The **ISPF Primary Option Menu** is displayed.
5. Access SDSF to view output from a job. To do this,
   a. Type M at the **Option** prompt and press Enter.

   ![ISPF Primary Option Menu]

   **Option ==> M**

   F1=Help   F2=Split   F3=Exit   F7=Backward   F8=Forward   F9=Swap
   F10=Actions   F12=Cancel

   **Licensed Materials - Property of IBM**
   5650-ZOS Copyright IBM Corp. 1980, 2017.
   US Government Users Restricted Rights - Use, duplication or disclosure restricted by GSA ADP Schedule Contract with IBM Corp.

   b. Type 5 and press Enter.

**Option ====> S**

F1=Help  F2=Split  F3=Exit  F7=Backward  F8=Forward  F9=Swap
F10=Actions  F12=Cancel
6. To view the jobs in an active status, type DA at the command input prompt and press Enter. The jobs that are running are displayed.
7. To query the jobs that start with SDSF, type prefix **sdsf**; **owner** * at the command input prompt and press Enter.
8. To view the contents of the job, type S next to the job name SDSF and press Enter.

The contents of the job are displayed.
Close the 3270 Terminal window. In the next step, you will use the MVS Explorer to make changes to a data set.

**Editing a data set in MVS Explorer**

Use the MVS Explorer to create and edit a data set member and save the changes. The MVS Explorer view lets you browse the MVS file system by creating filters against data set names.

**Follow these steps:**

1. Click the Start menu on Zowe Desktop.
2. Scroll down to find the MVS Explorer icon and pin this application to the desktop for later use.
3. Click the **MVS Explorer** icon on the taskbar. The MVS Explorer opens. The **Filter** field is pre-filled with the user name. In this tutorial, the filter string is **IBMUSER**. All the data sets matching this filter are displayed. You can expand a data set name and see the members in it.
4. Enter `USER.Z23B.PARMLIB` in the **Filter** field to locate this data set and then click to expand it. Ensure that there is no extra space before the data set member name that you enter.

5. Right-click the `USER.Z23B.PARMLIB` data set and select **New Dataset Member**.

6. Enter **ZTRIAL** as the data set member name and click **OK** to create the data set member.

7. Click the data set member you just created and edit it by adding a new sentence, for example, **First change to Zowe zTrial**.

8. Click **SAVE** to save your edits.

   The following message **Save success for USER.Z23B.PARMLIB(ZTRIAL)** pops up quickly at the bottom of the MVS Explorer window, which indicates that your edits are successfully saved.

Leave the MVS Explorer window open; we will look at the contents of the data set in a later step. If asked to leave the page, choose **Stay on Page**. Next, you will use Zowe CLI to view and add another change to the same data set.

**Using the Zowe CLI to edit a data set**

Use Zowe CLI to download the same data set that you edited by using MVS Explorer in the previous step, edit it, and upload the changes to the mainframe.

Zowe CLI is a command-line interface that lets you interact with z/OS from various other platforms, such as cloud or distributed systems, to submit jobs, issue TSO and z/OS console commands, integrate z/OS actions into scripts, produce responses as JSON documents, and more. With this extensible and scriptable interface, you can tie in mainframes to distributed DevOps pipelines and build automation.
Follow these steps:

1. Start the Command Prompt or a terminal in your local desktop. In this tutorial, it's assumed that you use Windows Command Prompt.

2. (Optional) Issue the following command to view the top-level help descriptions.

   ```bash
   zowe --help
   ```

   **Tip:** The command `zowe` initiates the product on a command line. All Zowe CLI commands begin with `zowe`.

3. To list the data sets of USER, enter the following command:

   ```bash
   zowe zos-files list data-set "USER.*"
   ```

   The following data sets are listed.

   ```
   USER.BEG.CMPRST.
   USER.Z23B.GUIDO/Z23B
   USER.Z23B.CLI2
   USER.Z23B.IHSE
   USER.Z23B.ISPLLIB
   USER.Z23B.IEPLLIB
   USER.Z23B.LIBPLLIB
   USER.Z23B.LIB2PLLIB
   USER.Z23B.LINKLIB
   USER.Z23B.LOADLIB
   USER.Z23B.LPARMLIB
   USER.Z23B.MKGRD
   USER.Z23B.PARMLIB
   USER.Z23B.PROCLIB
   USER.Z23B.SYSGLOB
   USER.Z23B.SINESRC
   USER.Z23B.TESTLIB
   USER.Z23B.TLIB
   USER.Z23B.VMGRD
   USER.Z23B.VMPLLIB
   ```

4. To download all the data set members of USER.Z23B.PARMLIB, enter the following command:

   ```bash
   zowe zos-files download all-members "USER.Z23B.PARMLIB"
   ```

   The message "Data set downloaded successfully" indicates that the data set members are downloaded. A file hierarchy is added to your current directory.

   ```
   C:\Users\Administrator\zowe exe-files download all-members "USER.Z23B.PARMLIB"
   Destination: USER/Z23B/parmlib
   Data set downloaded successfully.
   ```

5. To open the data set member named ZTRIAL in Visual Studio Code, issue the following command against the same directory where you issued the download command:

   ```bash
   code USER/Z23B/PARMLIB/ZTRIAL.txt
   ```

   Alternatively, navigate to the PARMLIB directory and issue `code ZTRIAL.txt`.

   The file opens in a text editor (in this example, VS Code). You will see the changes you made in the previous step by using the MVS Explorer.

6. Add the text `Second change to Zowe zTrial` to the file and then use `Ctrl+S` to save your edits.
7. Open the Command Prompt again and upload your changes to the mainframe by entering the following command:

```
zowe zos-files upload file-to-data-set USER/Z23B/PARMLIB/ZTRIAL.txt
"USER.Z23B.PARMLIB"
```

The following message indicates that you successfully uploaded your changes:

```
Data set uploaded successfully.
```

Congratulations! You used Zowe CLI to edit a data set member and upload the changes to mainframe.

Close the Command Prompt window. In the next step, you will open the MVS Explorer again to view the updates that you made to the data set in this procedure.

**Viewing the data set changes in MVS Explorer**

Use the MVS Explorer to view the data set changes from the previous step.

**Procedure**

1. Return to the Zowe Desktop and open the MVS Explorer application.
2. Locate the data set member `USER.Z23B.PARMLIB > ZTRIAL` and click the refresh icon. You will see the changes you just made by using Zowe CLI.

Congratulations! You explored several applications on the Zowe Desktop and learned how to work with them.

**Next steps**

Here are some next steps.

**Go deeper with Zowe**

In roughly 20 minutes, you used the MVS™ Explorer and Zowe CLI to edit the same data set member, and used the JES Explorer and the 3270 Terminal to query the same JES job with filters, all without leaving Zowe. Now that you're familiar with Zowe components, you can continue to learn more about the project. Zowe also offers many more plug-ins for both Zowe Desktop and Zowe CLI.

For more information, see the Using the Zowe Desktop on page 161.

For a complete list of available CLI commands, explore the Zowe CLI Zowe CLI command reference on page 175.

**Try the Extending Zowe scenarios**

You can add your own application plug-ins to Zowe. See how easy it is to extend Zowe to create your own APIs and applications by reading the Onboarding Overview on page 211 section.

**Give feedback**

Did you find this tutorial useful? You can tell us what you think about this tutorial via an online survey.
If you encounter any problems or have an idea for improving this tutorial, you can create a GitHub issue here.

Using the Zowe Desktop

You can use the Zowe™ Application Framework to create application plug-ins for the Zowe Desktop. For more information, see Overview on page 242.

Navigating the Zowe Desktop

From the Zowe Desktop, you can access Zowe applications.

Accessing the Zowe Desktop

From a supported browser, open the Zowe Desktop at https://myhost:httpsPort/ZLUX/plugins/org.zowe.zlux.bootstrap/web/index.html where:

- `myHost` is the host on which you are running the Zowe Application Server.
- `httpsPort` is the value that was assigned to `node.https.port` in `zluxserver.json`. For example, if you run the Zowe Application Server on host `myhost` and the value that is assigned to `node.https.port` in `zluxserver.json` is 12345, you would specify https://myhost:12345/ZLUX/plugins/org.zowe.zlux.bootstrap/web/index.html.

Logging in and out of the Zowe Desktop

1. To log in, enter your mainframe credentials in the Username and Password fields.
2. Press Enter. Upon authentication of your user name and password, the desktop opens.

To log out, click the the avatar in the lower right corner and click Sign Out.

Changing user password

1. Click the personalization panel icon.

1. Click the Change Password icon.
2. Fill out the Old Password and New Password fields.
3. Upon successful password change, you will be taken to the desktop.

Updating an expired password

1. Upon logging in with an expired password, a screen will be displayed prompting you to change your password.
2. Enter and confirm your new password in the corresponding fields.
3. Upon successful password change, you will be taken to the desktop.

Pinning applications to the task bar

1. Click the Start menu.
2. Locate the application you want to pin.
3. Right-click the on the application icon and select Pin to taskbar.

Changing the desktop language

Use the Languages setting in the personalization panel to change the desktop language. After you change the language and restart Zowe, desktop menus and text display in the specified language. Applications that support the specified desktop language also display in that language.
1. Click the personalization icon in the lower right corner.
2. Click Languages.
3. In the Languages dialog, click a language, and then click Apply.
4. When you are prompted, restart Zowe.

**Zowe Desktop application plug-ins**

Application plug-ins are applications that you can use to access the mainframe and to perform various tasks. Developers can create application plug-ins using a sample application as a guide. The following application plug-ins are installed by default:

**Hello World Sample**
The Hello World sample application plug-in for developers demonstrates how to create a dataservice and how to create an application plug-in using Angular.

**IFrame Sample**
The IFrame sample application plug-in for developers demonstrates how to embed pre-made webpages within the desktop as an application and how an application can request an action of another application (see the source code for more information).

**z/OS Subsystems**
The z/OS Subsystems plug-in helps you find information about the important services on the mainframe, such as CICS, Db2, and IMS.

**3270 Terminal**
The 3270 Terminal plug-in provides a user interface that emulates the basic functions of IBM 3270 family terminals. On the "back end," the plug-in and the Zowe Application Server connect to any standard TN3270E server.

**VT Terminal**
The VT Terminal plug-in provides a user interface that emulates the basic functions of DEC VT family terminals. On the "back end," the plug-in and the Zowe Application Server connect to VT compatible hosts, such as z/OS UNIX System Services (USS), using standard network protocols.

**API Catalog**
The API Catalog plug-in lets you view API services that have been discovered by the API Mediation Layer. For more information about the API Mediation Layer, Discovery Service, and API Catalog, see Zowe overview on page 8.

**Editor**
With the Zowe Editor you can create and edit files on the system that Zowe serves.

**Workflows**
From the Workflows application plug-in you can create, manage, and use z/OSMF workflows to manage your system.

**JES Explorer**
Use this application to query JES jobs with filters, and view the related steps, files, and status. You can also purge jobs from this view.

**MVS Explorer**
Use this application to browse the MVS™ file system by using a high-level qualifier filter. With the MVS Explorer, you can complete the following tasks:
- List the members of partitioned data sets.
- Create new data sets using attributes or the attributes of an existing data set ("Allocate Like").
- Submit data sets that contain JCL to Job Entry Subsystem (JES).
- Edit sequential data sets and partitioned data set members with basic syntax highlighting and content assist for JCL and REXX.
• Conduct basic validation of record length when editing JCL.
• Delete data sets and members.
• Open data sets in full screen editor mode, which gives you a fully qualified link to that file. The link is then reusable for example in help tickets.

**USS Explorer**

Use this application to browse the USS files by using a path. With the USS Explorer, you can complete the following tasks:

• List files and folders.
• Create new files and folders.
• Edit files with basic syntax highlighting and content assist for JCL and REXX.
• Delete files and folders.

**Using the Workflows application plug-in**

The Workflows application plug-in is available from the Zowe Desktop Start menu. To launch Workflows, click the Start menu in the lower-left corner of the desktop and click the Workflows application plug-in icon. The Users/Tasks Workflows window opens.

**Logging on to the system**

If you are prompted to log on to the system, complete these steps:

1. Enter your user ID and password.
2. Click **Sign in**.

**Updating the data display**

To refresh the data on any tab, click in the upper right corner of the window.

**Configuration**

From the Configuration tab, you can view, add, and remove servers.

**Adding a z/OSMF server**

Complete these steps to add a new z/OSMF server:

1. Click the Configuration tab.
2. Click the plus sign (+) on the left side of the window.
3. In the Host field, type the name of the host.
4. In the Port field, type the port number.
5. Click **OK**.

**Testing a server connection**

To test the connection, click **Test**. When the server is online the Online indicator next to the server Host and Port is green.

**Setting a server as the default z/OSMF server**

Complete these steps to set a default z/OSMF server:

1. Click Set as default.
2. Enter your user ID and password.
3. Click **Sign in**.

**Note:** You must specify a default server.

**Removing a server**

To remove a server, click x next to the server that you want to remove.
Reload a server configuration
To reload a server configuration, click **Reload**.

Save a server configuration
To save a server configuration, click **Save**.

Workflows
To display all workflows on the system, click the **Workflows** tab.
You can sort the workflows based on the following information:

**Workflow**
The name of the workflow.

**Description**
The description of the workflow.

**Version**
The version number.

**Owner**
The user ID of the workflow owner.

**System**
The system identifier.

**Status**
The status of the workflow (**In progress** or **Completed**).

**Progress**
Indicates how much of the workflow has been completed based on the number of tasks completed.

Searching workflows
To locate a specific workflow, type a search string in the search box in the upper right corner of the window.

Defining a workflow
To define a workflow, complete these steps:

1. From the **Workflows** tab, click **Actions** > **New workflow**. (By default, the **Advanced Mode** check box is selected.)
2. In the **Name** field, specify a descriptive name for the workflow.
3. In the **Workflow definition file** field, specify the primary XML file for this workflow.
4. In the **System** field, specify a system.
5. In the **Owner** field, specify the user ID of the person that is responsible for assigning the tasks in the workflow.
   (To set the owner to the current user, select the **Set owner to current user** check box.)
6. Click **OK**.

Viewing tasks
To view the tasks associated with a workflow, click the **My Tasks** tab. Workflows that have assigned tasks are shown on the left side of the window. The task work area is on the right side of the window.

You can choose to view workflows that have **Pending** or **Completed** tasks or you can choose to view all workflows (**Pending** and **Completed**) and their tasks, regardless of the task status.

For each workflow, you can click the arrow to expand or collapse the task list. Assigned tasks display below each workflow. Hovering over each task displays more information about the task, such as the status and the owner.
Each task has an indicator of **PERFORM** (a step to be performed) or **CHECK** (Check the step that was performed). Clicking **CHECK** or **PERFORM** opens a work area on the right side of the window. When a task is complete, a green clipboard icon with a checkmark is displayed.

**Note:** If you are viewing tasks on a **Pending** or **Completed** tab, only those workflows that have tasks with a corresponding status, are displayed.

**Task work area**

When you click **CHECK** or **PERFORM**, a work area on the right side of the window opens to display the steps to complete the task. Expand or collapse the work area by clicking  

**Tip:** Hovering over the task description in the title bar of the work area window on the right side displays more information about the corresponding workflow and the step description.

**Performing a task**

1. To perform a task that has steps that are assigned to you, click **PERFORM**.
2. Use the work area to perform the steps associated with the selected task. Depending on the task, you might use an embedded tool (such as another application) or you might complete a series of steps to complete the task.
3. If there are multiple steps to perform, click **Next** to advance to the next step for the task.
4. Click **Finish**.

**Note:** When a task is complete, a green clipboard icon with a checkmark is displayed next to the task.

**Checking a task**

1. To check a task, click **CHECK**.
2. In the task work area, view the JESMSGLG, JESJCL, JESYSMSG, or SYSTSPRT output that is associated with the selected task.

**Managing tasks**

To manage a task in the **PERFORM** status, click  to the right of the task status. Choose from the following options:

**Properties**

Display the title and description of the task.

**Perform**

Perform the first step.

**Skip**

Skip this step.

**Override Complete**

Override the completion of the step. The selected step will be bypassed and will not be performed for this workflow. You must ensure that the step is performed manually.

**Assignment**

Opens the Manage Assignees window where authorized users can add or remove the user ID of the person that is assigned to the step.

**Return**

Remove ownership of the step.

**Viewing warnings**

To view any warning messages that were encountered, click the **Warnings** tab. A message is listed in this tab each time it is encountered.

To locate a specific message, type a search string in the search box in the upper right corner of the window.
You can sort the warning messages based on the following information.

**Message Code**
The message code that is associated with the warning.

**Description**
A description of the warning.

**Date**
The date of the warning.

**Corresponding Workflow**
The workflow that is associated with the warning.

**Using the Editor**
With the Zowe Editor, you can create and edit the many types of files.

**Specifying a language server**
To specify a language server, complete these steps:

1. From the **Language Server** menu, select **URL**.*
2. From the **Language Server Setting**, **Put your config here** area, paste your configuration.
3. Ensure that the **Enable Language Server** check box is selected.
4. Click **Save**.

**Specifying a language**
From the **Language** menu, select the language you want to use.

**Opening a directory**
To open a directory on the system, complete these steps:

1. From the **File** menu, select **Open Directory**. (Alternatively, you can click **Open Directory** in the File Explorer.)
2. From the **Open Directory**, **Input Your Directory** field, type the name of the directory you want to open. For example: `/u/zs1234`
3. Click **Open**.

The File Explorer on the left side of the window lists the folders and files in the specified directory. Clicking on a folder expands the tree. Clicking on a file opens a tab that displays the file contents.

**Creating a new file**
To create a new file, complete these steps:

1. From the **File** menu, select **New File**. The **New File** tab opens.
2. From the **New File**, **File Name** field, type the name of the file.
3. Click **Create**.

**Saving a file**
To save a file, click **File > Save**.

**Note:** To save all files, click **File > Save All** (or Ctrl+S).

**Using API Catalog**
As an application developer, use the API Catalog to view what services are running in the API Mediation Layer. Through the API Catalog, you can also view the associated API documentation corresponding to a service, descriptive information about the service, and the current state of the service. The tiles in the API Catalog can be
customized by changing values in the \texttt{apiml.catalog.tile} section defined in the \texttt{application.yml} of a service. A microservice that is onboarded to the API Mediation Layer and configured appropriately, registers automatically with the API Catalog and a tile for that service is added to the Catalog.

\textbf{Note:} For more information about how to configure the API Catalog in the \texttt{application.yml}, see: Add API Onboarding Configuration.

\section*{View Service Information and API Documentation in the API Catalog}

Use the API Catalog to view services, API documentation, descriptive information about the service, the current state of the service, service endpoints, and detailed descriptions of these endpoints.

\textbf{Note:} Verify that your service is running. At least one started and registered instance with the Discovery Service is needed for your service to be visible in the API Catalog.

\textbf{Follow these steps:}

1. Use the search bar to find the service that you are looking for. Services that belong to the same product family are displayed on the same tile.

   \textbf{Example:} Sample Applications, Endevor, SDK Application

2. Click the tile to view header information, the registered services under that family ID, and API documentation for that service.

\textbf{Notes:}

- The state of the service is indicated in the service tile on the dashboard page. If no instances of the service are currently running, the tile displays a message that no services are running.
- At least one instance of a service must be started and registered with the discovery service for it to be visible in the API Catalog. If the service that you are onboarding is running, and the corresponding API documentation is displayed, this API documentation is cached and remains visible even when the service and all service instances stop.
- Descriptive information about the service and a link to the home page of the service are displayed.

\textbf{Example:}
3. Expand the endpoint panel to see a detailed summary with responses and parameters of each endpoint, the endpoint description, and the full structure of the endpoint.

Example:

Notes:
• If a lock icon is visible on the right side of the endpoint panel, the endpoint requires authentication.
• The structure of the endpoint is displayed relative to the base URL.
• The URL path of the abbreviated endpoint relative to the base URL is displayed in the following format:

Example:
/api/v1/{yourServiceId}/{endpointName}

The path of the full URL that includes the base URL is also displayed in the following format:
https://hostName:basePort/api/v1/{yourServiceId}/{endpointName}

Both links target the same endpoint location.

Swagger "Try it out" functionality in the API Catalog

The API Catalog enables users to call service APIs through the Try it out functionality. There are 2 types of endpoints:

• Public endpoints
  Endpoints that are accessible without entering user credentials.
• **Protected endpoints**

Endpoints that are only accessible by entering user credentials. These endpoints are marked with a lock icon.

**Example:**

- **API Catalog**  Current state information
  - **GET**  `/containers`  Lists catalog dashboard tiles
  - **GET**  `/containers/{id}`  Retrieves a specific dashboard tile information

- **API Documentation**  Service documentation
  - **GET**  `/apidoc/{servicId}/{apiVersion}`  Retrieves the API documentation for a specific service version

**Note:** Before making requests to protected endpoints, authorize your session by clicking the lock icon and complete the required information in the Authorization modal shown below:

**Example:**

To demonstrate **Try it out**, we use the example of the Swagger Petstore.

**Example:**
Make a request

This section outlines the process for making a request.

Follow these steps:

1. Expand the POST Pet endpoint.
2. Click Try it out.

Example:

After you click Try it out, the example value in the Request Body field becomes editable.

3. In the Example Value field, change the first id value to a random value. Change the second name value to a value of your choice, such as the name of a pet.
4. Click **Execute**.

**Example:**

![API Catalog Swagger UI screenshot]

The API Catalog Swagger UI submits the request and shows the `curl` that was submitted. The Responses section shows the response.

**Example:**

![Responses screenshot]
Using Zowe CLI

The Zowe command line interface (CLI) can be used interactively from a command window on any computer on which it is installed.

**Tip:** If you want to use the CLI together with a screen reader to provide accessibility, we recommend using the Mac™ Terminal application enabled for Accessibility through System Preferences > Accessibility. On Windows™, adjust the Properties settings in Command Prompt. For other operating systems, or for alternative terminals, check the specification for the terminal to ensure that it meets accessibility requirements.

**Displaying Zowe CLI help**

Zowe™ CLI has a command-line help system that helps you to learn about the commands, actions, and options available in the product.

- [Top-level help](#) on page 173
- [Group, action, and object help](#) on page 174
- [Interactive web help](#) on page 175
- [Zowe CLI command reference](#) on page 175

**Top-level help**

To view top-level help, open a command-line and issue the following command:

```
zowe --help
```
Alternatively, issue the following command to display a full list of all available commands:

```
zowe --ac
```

**Tip:** All Zowe CLI commands begin with `zowe`.

**Group, action, and object help**

You can append `--help` to learn about a specific command group, action, or object.
For example, issue the following command to learn more about the create action in the zos-files group:

```
zowe zos-files create --help
```

**Interactive web help**

You can launch an interactive form of help in your Web browser. Web help is custom-generated to include commands for all currently installed plug-ins. Issue the following command:

```
zowe --help-web
```

**Tip:** Append `--help-web` to a specific command or action to launch directly into the appropriate Web help page.

**Zowe CLI command reference**

Command reference is available for download in three formats: a static copy of the interactive Web help, a ZIP file that contains the HTML web help, and a static PDF:

- Browse Online
- Download (ZIP)
- Download (PDF)

**Using the prompt for sensitive options**

Zowe CLI lets you enable a command-line "prompt" feature, which masks values on the screen as you type. You might choose to enable the prompt for sensitive credentials such as mainframe username or password.

You can enable the prompt on-demand, or choose to always prompt for a particular option.

**Enable prompt**

Enable on-demand prompting for arguments and options.

Follow these steps:

1. Begin typing a Zowe CLI command.
2. For the option(s) that you want to mask, insert the value "PROMPT*". For example, prompt for your password:

   ```
zowe zos-files list data-set "MY.DATASET.*" --host my.company.com --port 123 --user myusername123 --password "PROMPT*"
   ```

   The CLI prompts you to enter a value for the `--password` field.
3. Enter a value to complete the command.

   **Tip:** Enter the value carefully. The backspace key does not work in prompt mode.

**Always prompt**

You can configure your environment so that the CLI always prompts for a particular option, such as `--password`.

To enable the feature, set an environment variable named `ZOWE_OPT_PASSWORD` with the value "PROMPT*". With the environment variable set, the CLI automatically enables the prompt when you omit a required `--password` value.

**Tip** The procedure for setting environment variables is dependent on your operating systems. Refer to documentation for your OS to learn about setting environment variables.

**Change the keyword for prompt**

The default keyword that enables prompting in Zowe CLI is "PROMPT*". You might want to change the keyword if there is a chance that "PROMPT*" could exist as a valid value for the field. For example, if you mask the `data-set` argument and are working with real mainframe data sets that begin with the characters "PROMPT*".

To configure the keyword, choose a new value. Then define the value to to the environment variable on your computer named `ZOWE_PROMPT_PHRASE`. 
**Zowe CLI command groups**

Zowe CLI contains command groups that focus on specific business processes. For example, the `zos-files` command group provides the ability to interact with mainframe data sets. This article provides you with a brief synopsis of the tasks that you can perform with each group. For more information, see Displaying Zowe CLI help on page 173.

The commands available in the product are organized in a hierarchical structure. Command groups (for example, `zos-files`) contain actions (for example, `create`) that let you perform actions on specific objects (for example, a specific type of data set). For each action that you perform on an object, you can specify options that affect the operation of the command.

**Important!** Before you issue these commands, verify that you completed the steps in Creating Zowe CLI profiles on page 137 and Test Connection to z/OSMF to help ensure that Zowe CLI can communicate with z/OS systems.

Zowe CLI contains the following command groups:

**plugins**

The plugins command group lets you install and manage third-party plug-ins for the product. Plug-ins extend the functionality of Zowe CLI in the form of new commands.

With the plugins command group, you can perform the following tasks:

- Install or uninstall third-party plug-ins.
- Display a list of installed plug-ins.
- Validate that a plug-in integrates with the base product properly.

**Note:** For more information about `plugins` syntax, actions, and options, open Zowe CLI and issue the following command:

```
zowe plugins -h
```

**profiles**

The profiles command group lets you create and manage profiles for use with other Zowe CLI command groups. Profiles allow you to issue commands to different mainframe systems quickly, without specifying your connection details with every command.

With the profiles command group, you can perform the following tasks:

- Create, update, and delete profiles for any Zowe CLI command group that supports profiles.
- Set the default profile to be used within any command group.
- List profile names and details for any command group, including the default active profile.

**Note:** For more information about `profiles` syntax, actions, and options, open Zowe CLI, and issue the following command:

```
zowe profiles -h
```

**provisioning**

The provisioning command group lets you perform IBM z/OSMF provisioning tasks with templates and provisioned instances from Zowe CLI.

With the provisioning command group, you can perform the following tasks:

- Provision cloud instances using z/OSMF Software Services templates.
- List information about the available z/OSMF Service Catalog published templates and the templates that you used to publish cloud instances.
- List summary information about the templates that you used to provision cloud instances. You can filter the information by application (for example, DB2 and CICS) and by the external name of the provisioned instances.
• List detail information about the variables used (and their corresponding values) on named, published cloud instances.

**Note:** For more information about provisioning syntax, actions, and options, open Zowe CLI and issue the following command:

```
zowe provisioning -h
```

**zos-console**

The zos-console command group lets you issue commands to the z/OS console by establishing an extended Multiple Console Support (MCS) console.

With the zos-console command group, you can perform the following tasks: **Important!** Before you issue z/OS console commands with Zowe CLI, security administrators should ensure that they provide access to commands that are appropriate for your organization.

• Issue commands to the z/OS console.
• Collect command responses and continue to collect solicited command responses on-demand.

**Note:** For more information about zos-console syntax, actions, and options, open Zowe CLI and issue the following command:

```
zowe zos-console -h
```

**zos-files**

The zos-files command group lets you interact with data sets on z/OS systems.

With the zos-files command group, you can perform the following tasks:

• Create partitioned data sets (PDS) with members, physical sequential data sets (PS), and other types of data sets from templates. You can specify options to customize the data sets you create.
• Download mainframe data sets and edit them locally in your preferred Integrated Development Environment (IDE).
• Upload local files to mainframe data sets.
• List available mainframe data sets.
• Interact with VSAM data sets directly, or invoke Access Methods Services (IDCAMS) to work with VSAM data sets.

**Note:** For more information about zos-files syntax, actions, and options, open Zowe CLI and issue the following command:

```
zowe zos-files -h
```

**zos-jobs**

The zos-jobs command group lets you submit jobs and interact with jobs on z/OS systems.

With the zos-jobs command group, you can perform the following tasks:

• Submit jobs from JCL that resides on the mainframe or a local file.
• List jobs and spool files for a job.
• View the status of a job or view a spool file from a job.

**Note:** For more information about zos-jobs syntax, actions, and options, open Zowe CLI and issue the following command:

```
zowe zos-jobs -h
```
**zos-uss**

The zos-uss command group lets you issue Unix System Services shell commands by establishing an SSH connection to an SSH server.

With the zos-uss command group, you can perform the following task: **Important**! Before you issue z/OS UNIX System Services commands with Zowe CLI, security administrators must provide access for your user ID to login via SSH.

- Issue z/OS UNIX System Services shell commands over an SSH connection and stream back the response.

**Note:** For more information about zos-uss syntax, actions, and options, open Zowe CLI and issue the following command:

```
zowe zos-uss -h
```

**zos-workflows**

The zos-workflows command group lets you create and manage z/OSMF workflows on a z/OS system.

With the zos-workflows command group, you can perform the following tasks:

- Create or register a z/OSMF workflow based on the properties on a z/OS system
- Start a z/OSMF workflow on a z/OS system.
- Delete or remove a z/OSMF workflow from a z/OS system.
- List the z/OSMF workflows for a system or sysplex.

**Note:** For more information about zos-workflows syntax, actions, and options, open Zowe CLI and issue the following command:

```
zowe zos-workflows -h
```

**zos-tso**

The zos-tso command group lets you issue TSO commands and interact with TSO address spaces on z/OS systems.

With the zos-tso command group, you can perform the following tasks:

- Execute REXX scripts
- Create a TSO address space and issue TSO commands to the address space.
- Review TSO command response data in Zowe CLI.

**Note:** For more information about zos-tso syntax, actions, and options, open Zowe CLI and issue the following command:

```
zowe zos-tso -h
```

**zosmf**

The zosmf command group lets you work with Zowe CLI profiles and get general information about z/OSMF.

With the zosmf command group, you can perform the following tasks:

- Create and manage your Zowe CLI zosmf profiles. Profiles let you store configuration information for use on multiple commands. You can create a profile that contains your username, password, and connection details for a particular mainframe system, then reuse that profile to avoid typing it again on every command. You can switch between profiles to quickly target different mainframe subsystems. For more information, see Creating Zowe CLI profiles on page 137.
- Verify that your profiles are set up correctly to communicate with z/OSMF on your system. For more information, see Test Connection to z/OSMF.
- Get information about the current z/OSMF version, host, port, and plug-ins installed on your system.
Note: For more information about zosmf syntax, actions, and options, open Zowe CLI and issue the following command:

```
zowe zosmf -h
```

Writing scripts to automate mainframe actions

You can combine multiple Zowe CLI commands in bash or shell scripts to automate actions on z/OS. You can implement scripts to enhance your development workflow, automate repetitive test or build tasks, and orchestrate mainframe actions from continuous integration/continuous deployment (CI/CD) tools such as Jenkins or TravisCI.

- Writing a Script on page 179
- Example: Clean up Temporary Data Sets
- Example: Submit Jobs and Save Spool Output

Writing a Script

Write a script that executes multiple CLI commands.

Note: The type of script that you write depends on the programming languages that you use and the environment where the script is executed. The following procedure is a general guide to Zowe CLI scripts, but you might need to refer to third-party documentation to learn more about scripting in general.

Follow these steps:

1. Create a new file on your computer with the extension .sh. For example, `testScript.sh`.
   
   Note: On Linux, an extension is not required. You make the file executable by issuing the command `chmod u+x testScript`.

2. At the top of the file, specify the interpreter that your script requires. For example, type `#!/bin/sh` or `#!/bin/bash`.
   
   Note: The command terminal that you use to execute the script depends on what you specify at the top of your script. Bash scripts require a bash interpreter (bash terminal), while shell scripts can be run from any terminal.

3. Write a script using a series of Zowe CLI commands.
   
   Tip: You can incorporate commands from other command-line tools in the same script. You might choose to "pipe" the output of one command into another command.

4. From the appropriate command terminal, issue a command to execute the script. The command you use to execute script varies by operating system.

The script runs and prints the output in your terminal. You can run scripts manually, or include them in your automated testing and delivery pipelines.

Example: Clean up Temporary Data Sets

The script in this example lists specified data sets, then loops through the list of data sets and deletes each file. You can use a similar script to clean up temporary data sets after use.

Note: This script must be run from a bash terminal.

```
#!/bin/bash
set -e
# Project cleanup script - deletes temporary project data sets
# Obtain the list of temporary project data sets
dslist=$(zowe files ls ds "my.project.ds*")
# Delete each data set in the list
IFS="\n" for ds in $dslist
do
echo "Deleting Temporary Project Dataset: $ds"
zowe files delete ds "$ds" -f
done
```
Example: Submit Jobs and Save Spool Output

The script in this example submits a job, waits for the job to enter output status, and saves the spool files to local files on your computer.

Note: This script must be run from a bash terminal.

```bash
#!/bin/env bash
#submit our job
jobid=$(zowe zos-jobs submit data-set "boech02.public.cntl(iefbr14)" --rff jobid --rft string)
echo "Submitted our job, JOB ID is $jobid"
#wait for job to go to output
status="UNKNOWN"
while [[ "$status" != "OUTPUT" ]]; do
    echo "Checking status of job $jobid"
    status=$(zowe zos-jobs view job-status-by-jobid "$jobid" --rff status --rft string)
    echo "Current status is $status"
    sleep 5s
done;
echo "Job completed in OUTPUT status. Final result of job:"
zowe zos-jobs view job-status-by-jobid "$jobid"

# get a list of all of the spool files for our job now that it's in output
spool_ids=$(zowe zos-jobs list spool-files-by-jobid "$jobid" --rff id --rft table)
# save each spool ID to a custom file name
while read -r id; do
    zowe zos-jobs view spool-file-by-id "$jobid" "$id" > ./${jobid}_spool_${id}.txt
    echo "Saved spool DD to ./${jobid}_spool_${id}.txt"
done <<< "$spool_ids"
```

Zowe CLI extensions and plug-ins

Extending Zowe CLI

You can install plug-ins to extend the capabilities of Zowe™ CLI. Plug-ins CLI to third-party applications are also available, such as Visual Studio Code Extension for Zowe (powered by Zowe CLI). Plug-ins add functionality to the product in the form of new command groups, actions, objects, and options.

Important! Plug-ins can gain control of your CLI application legitimately during the execution of every command. Install third-party plug-ins at your own risk. We make no warranties regarding the use of third-party plug-ins.

- Installing Zowe CLI plug-ins on page 181
- IBM® CICS® Plug-in for Zowe CLI on page 185
- IBM® Db2® Database Plug-in for Zowe CLI on page 186
- IBM® z/OS FTP Plug-in for Zowe CLI on page 188
- IBM® IMS™ Plug-in for Zowe CLI on page 189
- IBM® MQ Plug-in for Zowe CLI on page 190
- Secure Credential Store Plug-in for Zowe CLI on page 191
- Zowe Explorer Extension for VSCode on page 193

Software requirements for Zowe CLI plug-ins

Before you use Zowe™ CLI plug-ins, complete the following steps:
**Important!** You can perform the required configurations for the plug-ins that you want to use before or after you install the plug-ins. However, if you do not perform the required configurations, the plug-ins will not function as designed.

<table>
<thead>
<tr>
<th>Plug-in</th>
<th>Required Configurations</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>IBM® CICS® Plug-in for Zowe CLI on page 185</strong></td>
<td>• Ensure that IBM CICS Transaction Server v5.2 or later is installed and running in your mainframe environment</td>
</tr>
<tr>
<td></td>
<td>• IBM CICS Management Client Interface (CMCI) is configured and running in your CICS region.</td>
</tr>
<tr>
<td><strong>IBM® Db2® Database Plug-in for Zowe CLI on page 186</strong></td>
<td>• Download and prepare the ODBC driver (required for only package installations) and address the licensing requirements.</td>
</tr>
<tr>
<td></td>
<td>• (MacOS) Download and Install Xcode.</td>
</tr>
<tr>
<td><strong>IBM® z/OS FTP Plug-in for Zowe CLI on page 188</strong></td>
<td>• Ensure that z/OS FTP service is enabled and configured with JESINTERFACELEVEL = 2.</td>
</tr>
<tr>
<td></td>
<td>• FTP over SSL is recommended.</td>
</tr>
<tr>
<td><strong>IBM® IMS™ Plug-in for Zowe CLI on page 189</strong></td>
<td>• Ensure that IBM® IMS™ v14.1.0 or later is installed and running in your mainframe environment.</td>
</tr>
<tr>
<td></td>
<td>• Configure IBM® IMS™ Connect.</td>
</tr>
<tr>
<td></td>
<td>• Configure IBM IMS Operations APIs to enable communication between the CLI and the IMS instance.</td>
</tr>
<tr>
<td><strong>IBM® MQ Plug-in for Zowe CLI on page 190</strong></td>
<td>• Ensure that IBM® MQ™ v9.1.0 or later is installed and running in your mainframe environment. Please read this blog for more information: Exposing the MQ REST API via the Zowe API Mediation Layer</td>
</tr>
<tr>
<td><strong>Secure Credential Store Plug-in for Zowe CLI on page 191</strong></td>
<td>• (Graphical Linux) Install gnome-keyring and libsecret on your computer.</td>
</tr>
<tr>
<td></td>
<td>• There are additional requirements for headless Linux systems. See the SCS plug-in Readme for details.</td>
</tr>
</tbody>
</table>

**Important!** You can perform the required configurations for the plug-ins that you want to use before or after you install the plug-ins. However, if you do not perform the required configurations, the plug-ins will not function as designed.

### Installing Zowe CLI plug-ins

Use commands in the plugins command group to install and manage Zowe™ CLI plug-ins.

**Important!** Plug-ins can gain control of your CLI application legitimately during the execution of commands. Install third-party plug-ins at your own risk. We make no warranties regarding the use of third-party plug-ins.

You can install the following Zowe plug-ins:

- IBM® CICS® Plug-in for Zowe CLI
- IBM® Db2® Plug-in for Zowe CLI
- Third-party Zowe Conformant Plug-ins

Use either of the following methods to install plug-ins:
- Install from an online NPM registry. Use this method when your computer can access the Internet.

  For more information, see Installing plug-ins from an online registry on page 182.

- Install from a local package. With this method, you download and install the plug-ins from a bundled set of .tgz files. Use this method when your computer cannot access the Internet.

  For more information, see Installing plug-ins from a local package on page 182.

### Installing plug-ins from an online registry

Install Zowe CLI plug-ins using npm commands on Windows, Mac, and Linux. The procedures in this article assume that you previously installed the core CLI.

**Follow these steps:**

1. Meet the Software requirements for Zowe CLI plug-ins on page 180 that you install.
2. Issue the following command to install a plug-in from public npm:

   ```bash
   zowe plugins install <my-plugin>
   ```

   **Note:** Replace `<my-plugin>` with the installation command syntax in the following table:

<table>
<thead>
<tr>
<th>Plug-in</th>
<th>Installation Command Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM CICS Plug-in for Zowe CLI</td>
<td>@zowe/cics-for-zowe-cli@zowe-v1-lts</td>
</tr>
<tr>
<td>IBM Db2 Plug-in for Zowe CLI</td>
<td>@zowe/db2-for-zowe-cli@zowe-v1-lts</td>
</tr>
<tr>
<td>IBM z/OS FTP Plug-in for Zowe CLI</td>
<td>@zowe/zos-ftp-for-zowe-cli@zowe-v1-lts</td>
</tr>
<tr>
<td>IBM IMS Plug-in for Zowe CLI</td>
<td>@zowe/ims-for-zowe-cli@zowe-v1-lts</td>
</tr>
<tr>
<td>IBM MQ Plug-in for Zowe CLI</td>
<td>@zowe/mq-for-zowe-cli@zowe-v1-lts</td>
</tr>
<tr>
<td>Secure Credential Store Plug-in for Zowe CLI</td>
<td>@zowe/secure-credential-store-for-zowe-cli@zowe-v1-lts</td>
</tr>
</tbody>
</table>

3. (Optional) Issue the following command to install two or more plug-ins using one command. Separate the `<my-plugin>` names with one space.

   ```bash
   zowe plugins install <@zowe/my-plugin1> <@zowe/my-plugin2> <@zowe/my-plugin3> ...
   ```

   **Note:** The IBM Db2 Plug-in for Zowe CLI requires additional licensing and ODBC driver configurations. If you installed the DB2 plug-in, see IBM® Db2® Database Plug-in for Zowe CLI on page 186.

You installed Zowe CLI plug-ins.

### Installing plug-ins from a local package

Install plug-ins from a local package on any computer that has limited or no access to the Internet. The procedure assumes that you previously installed the core CLI.

**Follow these steps:**

1. Meet the Software requirements for Zowe CLI plug-ins on page 180 that you want to install.
2. Obtain the installation files.

   From the Zowe Download website, click Download Zowe CLI to download the Zowe CLI installation package named `zowe-cli-package-*v*.*r*.*m*.zip` to your computer.

   **Note:** `v` indicates the version, `r` indicates the release number, and `m` indicates the modification number.
3. Open a command-line window, such as Windows Command Prompt. Browse to the directory where you downloaded the Zowe CLI installation package (.zip file). Issue the following command, or use your preferred method to unzip the files:

   ```
   unzip zowe-cli-package-v.r.m.zip
   ```

   **Example:**

   ```
   unzip zowe-cli-package-1.9.0.zip
   ```

   By default, the unzip command extracts the contents of the zip file to the directory where you downloaded the .zip file. You can extract the contents of the zip file to your preferred location.

4. Issue the following command against the extracted directory to install each available plug-in:

   ```
   zowe plugins install <my-plugin>
   ```

   Replace `<my-plugin>` with the .tgz file name listed in the following table:

<table>
<thead>
<tr>
<th>Plug-in</th>
<th>.tgz File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM CICS Plug-in for Zowe CLI</td>
<td>cics-for-zowe-cli.tgz</td>
</tr>
<tr>
<td>IBM Db2 Plug-in for Zowe CLI</td>
<td>db2-for-zowe-cli.tgz</td>
</tr>
<tr>
<td>IBM z/OS FTP Plug-in for Zowe CLI</td>
<td>zos-ftp-for-zowe-cli.tgz</td>
</tr>
<tr>
<td>IBM IMS Plug-in for Zowe CLI</td>
<td>imsi-for-zowe-cli.tgz</td>
</tr>
<tr>
<td>IBM MQ Plug-in for Zowe CLI</td>
<td>mq-for-zowe-cli.tgz</td>
</tr>
<tr>
<td>Secure Credential Store Plug-in for Zowe CLI</td>
<td>secure-credential-store-for-zowe-cli.tgz</td>
</tr>
</tbody>
</table>

You installed Zowe CLI plug-ins.

**Validating plug-ins**

Issue the plug-in validation command to run tests against all plug-ins (or against a plug-in that you specify) to verify that the plug-ins integrate properly with Zowe CLI. The tests confirm that the plug-in does not conflict with existing command groups in the base application. The command response provides you with details or error messages about how the plug-ins integrate with Zowe CLI.

The `validate` command has the following syntax:

   ```
   zowe plugins validate [plugin]
   ```

   - **[plugin]** (Optional) Specifies the name of the plug-in that you want to validate. If you do not specify a plug-in name, the command validates all installed plug-ins. The name of the plug-in is not always the same as the name of the NPM package.

<table>
<thead>
<tr>
<th>Plug-in</th>
<th>Installation Command Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM CICS Plug-in for Zowe CLI</td>
<td>@zowe/cics-for-zowe-cli</td>
</tr>
<tr>
<td>IBM Db2 Plug-in for Zowe CLI</td>
<td>@zowe/db2-for-zowe-cli</td>
</tr>
<tr>
<td>IBM z/OS FTP Plug-in for Zowe CLI</td>
<td>@zowe/zos-ftp-for-zowe-cli</td>
</tr>
<tr>
<td>IBM IMS Plug-in for Zowe CLI</td>
<td>@zowe/ims-for-zowe-cli</td>
</tr>
<tr>
<td>IBM MQ Plug-in for Zowe CLI</td>
<td>@zowe/mq-for-zowe-cli</td>
</tr>
</tbody>
</table>
Plug-in | Installation Command Syntax
---|---
Secure Credential Store Plug-in for Zowe CLI | @zowe/secure-credential-store-for-zowe-cli

**Examples: Validate plug-ins**

- The following example illustrates the syntax to use to validate the IBM CICS Plug-in for Zowe CLI:
  
  ```
  zowe plugins validate @zowe/cics
  ```

- The following example illustrates the syntax to use to validate all installed plug-ins:

  ```
  zowe plugins validate
  ```

**Updating plug-ins**

You can update Zowe CLI plug-ins from an online registry or from a local package.

**Update plug-ins from an online registry**

Issue the `update` command to install the latest stable version or a specific version of a plug-in that you installed previously. The `update` command has the following syntax:

```
zowe plugins update [plugin...] [--registry <registry>]
```

- Specifies the name of an installed plug-in that you want to update. The name of the plug-in is not always the same as the name of the NPM package. You can use npm semantic versioning to specify a plug-in version to which to update. For more information, see npm semver.
- `[--registry <registry>]`

  (Optional) Specifies a registry URL that is different from the registry URL of the original installation.

**Examples: Update plug-ins**

The following example illustrates the syntax to use to update an installed plug-in to the latest version:

```
zowe plugins update @zowe/my-plugin@zowe-v1-lts
```

The following example illustrates the syntax to use to update a plug-in to a specific version:

```
zowe plugins update @zowe/my-plugin@"^1.2.3"
```

**Update plug-ins from a local package**

You can update plug-ins from a local package. You acquire the media from the Zowe Download website and update the plug-ins using the `zowe plugins install` command.

To update plug-ins from a local package, follow the steps described in Installing plug-ins from a local package on page 182.

**Uninstall Plug-ins**

Issue the `uninstall` command to uninstall plug-ins from Zowe CLI. After the uninstall process completes successfully, the product no longer contains the plug-in configuration.

The uninstall command contains the following syntax:

```
zowe plugins uninstall [plugin]
```
• [plugin]
  Specifies the name of the plug-in that you want to uninstall.

The following table describes the uninstallation command syntax for each plug-in:

<table>
<thead>
<tr>
<th>Plugin Name</th>
<th>Installation Command Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM CICS Plug-in for Zowe CLI</td>
<td>@zowe/cics-for-zowe-cli</td>
</tr>
<tr>
<td>IBM Db2 Plug-in for Zowe CLI</td>
<td>@zowe/db2-for-zowe-cli</td>
</tr>
<tr>
<td>IBM z/OS FTP Plug-in for Zowe CLI</td>
<td>@zowe/zos-ftp-for-zowe-cli</td>
</tr>
<tr>
<td>IBM IMS Plug-in for Zowe CLI</td>
<td>@zowe/ims-for-zowe-cli</td>
</tr>
<tr>
<td>IBM MQ Plug-in for Zowe CLI</td>
<td>@zowe/mq-for-zowe-cli</td>
</tr>
<tr>
<td>Secure Credential Store Plug-in for Zowe CLI</td>
<td>@zowe/secure-credential-store-for-zowe-cli</td>
</tr>
</tbody>
</table>

Example:

The following example illustrates the command to uninstall the CICS plug-in:

```
zowe plugins uninstall @zowe/cics
```

**IBM® CICS® Plug-in for Zowe CLI**

The IBM® CICS® Plug-in for Zowe™ CLI lets you extend Zowe CLI to interact with CICS programs and transactions. The plug-in uses the IBM CICS® Management Client Interface (CMCI) API to achieve the interaction with CICS. For more information, see [CICS management client interface](https://www.ibm.com/support/knowledgecenter) on the IBM Knowledge Center.

- [Use cases](#) on page 185
- [Commands](#) on page 185
- [Software requirements](#) on page 186
- [Installing](#) on page 186
- [Creating a user profile](#) on page 186

**Use cases**

As an application developer, you can use the plug-in to perform the following tasks:

- Deploy code changes to CICS applications that were developed with COBOL.
- Deploy changes to CICS regions for testing or delivery. See the [Commands](#) on page 185 for an example of how you can define programs to CICS to assist with testing and delivery.
- Automate CICS interaction steps in your CI/CD pipeline with Jenkins Automation Server or TravisCI.
- Deploy build artifacts to CICS regions.
- Alter, copy, define, delete, discard, and install CICS resources and resource definitions.

**Commands**

For detailed documentation on commands, actions, and options available in this plug-in, see our [Web Help](https://www.ibm.com/support/knowledgecenter). It is available for download in three formats: a PDF document, an interactive online version, and a ZIP file containing the HTML for the online version.

- [Browse Online](#)
- [Download (ZIP)](#)
- [Download (PDF)](#)
Software requirements

Before you install the plug-in, meet the software requirements in Software requirements for Zowe CLI plug-ins on page 180.

Installing

Use one of the following methods to install or update the plug-in:

- Installing plug-ins from an online registry on page 182
- Installing plug-ins from a local package on page 182

Creating a user profile

You can set up a CICS profile to avoid typing your connection details on every command. The profile contains your host, port, username, and password for the CMCI instance of your choice. You can create multiple profiles and switch between them if necessary. Issue the following command to create a cics profile:

```
zowe profiles create cics <profile name> -H <host> -P <port> -u <user> -p <password>
```

The plug-in uses HTTPS by default. Use the optional flag `--protocol http` to override the default with HTTP.

Note: For more information, issue the command `zowe profiles create cics --help`

IBM® Db2® Database Plug-in for Zowe CLI

The IBM® Db2® Database Plug-in for Zowe™ CLI lets you interact with Db2 for z/OS to perform tasks through Zowe CLI and integrate with modern development tools. The plug-in also lets you interact with Db2 to advance continuous integration and to validate product quality and stability.

Zowe CLI Plug-in for IBM Db2 Database lets you execute SQL statements against a Db2 region, export a Db2 table, and call a stored procedure. The plug-in also exposes its API so that the plug-in can be used directly in other products.

Use cases

As an application developer, you can use Zowe CLI Plug-in for IBM DB2 Database to perform the following tasks:

- Execute SQL and interact with databases.
- Execute a file with SQL statements.
- Export tables to a local file on your computer in SQL format.
- Call a stored procedure and pass parameters.

Commands

For detailed documentation on commands, actions, and options available in this plug-in, see our Web Help. It is available for download in three formats: a PDF document, an interactive online version, and a ZIP file containing the HTML for the online version.

- Browse Online
- Download (ZIP)
- Download (PDF)

Software requirements

Before you install the plug-in, meet the software requirements in Software requirements for Zowe CLI plug-ins on page 180.

Installing

Use one of the following methods to install the Zowe CLI Plug-in for IBM Db2 Database:
• Installing from an online registry on page 187
• Installing from a local package on page 187

Installing from an online registry

If you installed Zowe CLI from online registry, complete the following steps:

1. Open a commandline window and issue the following command:

   ```
   zowe plugins install @zowe/db2-for-zowe-cli@zowe-v1-lts
   ```

2. Addressing the license requirement on page 187 to begin using the plug-in.

Installing from a local package

Follow these procedures if you downloaded the Zowe installation package:

Downloading the ODBC driver

Download the ODBC driver before you install the Db2 plug-in.

Follow these steps:

1. Download the ODBC CLI Driver. Use the table within the download URL to select the correct CLI Driver for your platform and architecture.
2. Create a new directory named odbc_cli on your computer. Remember the path to the new directory. You will need to provide the full path to this directory immediately before you install the Db2 plug-in.
3. Place the ODBC driver in the odbc_cli folder. Do not extract the ODBC driver.

You downloaded and prepared to use the ODBC driver successfully. Proceed to install the plug-in to Zowe CLI.

Installing the plug-in

Now that the Db2 ODBC CLI driver is downloaded, set the IBM_DB_INSTALLER_URL environment variable and install the Db2 plug-in to Zowe CLI.

Follow these steps:

1. Open a command line window and change the directory to the location where you extracted the zowe-cli-bundle.zip file. If you do not have the zowe-cli-bundle.zip file, see the topic Install Zowe CLI from local package in Installing Zowe CLI on page 116 for information about how to obtain and extract it.
2. From a command line window, set the IBM_DB_INSTALLER_URL environment variable by issuing the following command:
   - Windows operating systems:
     ```
     set IBM_DB_INSTALLER_URL=<path_to_your_odbc_folder>/odbc_cli
     ```
   - Linux and Mac operating systems:
     ```
     export IBM_DB_INSTALLER_URL=<path_to_your_odbc_folder>/odbc_cli
     ```

   For example, if you downloaded the Windows x64 driver (ntx64_odbc_cli.zip) to C:\odbc_cli, you would issue the following command:
   ```
   set IBM_DB_INSTALLER_URL=C:\odbc_cli
   ```
3. Issue the following command to install the plug-in:

   ```
   zowe plugins install zowe-db2.tgz
   ```
4. Addressing the license requirement on page 187 to begin using the plug-in.

Addressing the license requirement

The following steps are required for both the registry and offline package installation methods:
1. Locate your client copy of the Db2 license. You must have a properly licensed and configured Db2 instance for the Db2 plugin to successfully connect to Db2 on z/OS.

   **Note:** The license must be of version 11.1 if the Db2 server is not `db2connectactivated`. You can buy a db2connect license from IBM. The connectivity can be enabled either on server using `db2connectactivate` utility or on client using client side license file. To know more about DB2 license and purchasing cost, please contact IBM Customer Support.

2. Copy your Db2 license file and place it in the following directory.

   - **Windows:**
     ```
     <zowe_home>\plugins\installed\node_modules\@zowe\db2\node_modules\ibm_db\installer\clidriver\license
     ```
   - **Linux:**
     ```
     <zowe_home>/plugins/installed/lib/node_modules/@zowe/db2/node_modules/ibm_db/installer/clidriver/license
     ```

   **Tip:** By default, `<zowe_home>` is set to `~/.zowe` on *NIX systems, and `C:\Users\<Your_User>\.zowe` on Windows systems.

   After the license is copied, you can use the Db2 plugin functionality.

**Creating a user profile**

Before you start using the IBM Db2 plug-in, create a profile.

Issue the command `DISPLAY DDF` in the SPUFI or ask your DBA for the following information:

- The Db2 server host name
- The Db2 server port number
- The database name (you can also use the location)
- The user name
- The password
- If your Db2 systems use a secure connection, you can also provide an SSL/TSL certificate file.

To create a db2 profile in Zowe CLI, issue the following command with your connection details for the Db2 instance:

```bash
zowe profiles create db2 <profile name> -H <host> -P <port> -d <database> -u <user> -p <password>
```

**Note** For more information, issue the command `zowe profiles create db2-profile --help`

**IBM® z/OS FTP Plug-in for Zowe CLI**

The IBM® z/OS FTP Plug-in for Zowe™ CLI lets you extend Zowe CLI to access z/OS datasets, USS files, and submit JCL. The plug-in uses the z/OS FTP service to achieve the interaction with z/OS.

- **Use cases** on page 188
- **Commands** on page 189
- **Software requirements** on page 189
- **Installing** on page 189
- **Creating a user profile**

**Use cases**

As a z/OS user, you can use the plug-in to perform the following tasks:

- List, view, rename, and download z/OS datasets or USS files.
- Upload local files or `stdin` to z/OS datasets or USS files.
• List, view, and download job status or job spool files.
• Delete a z/OS dataset, USS file, or job.

Commands
For detailed documentation on commands, actions, and options available in this plug-in, see our Web Help. It is available for download in three formats: a PDF document, an interactive online version, and a ZIP file containing the HTML for the online version.

• Browse Online
• Download (ZIP)
• Download (PDF)

Software requirements
Before you install the plug-in, meet the software requirements in Software requirements for Zowe CLI plug-ins on page 180.

Installing
Use one of the following methods to install or update the plug-in:

• Installing plug-ins from an online registry on page 182
• Installing plug-ins from a local package on page 182

Create a User Profile
You can create a zftp user profile to avoid typing your connection details on every command. A zftp profile contains the host, port, username, and password for the z/OS instance to which you want to connect. You can create multiple profiles and switch between them as needed.

Issue the following command:

```
zowe profiles create zftp <profile name> -H <host> -u <user> -p <password> -P <port>
```

The result of the command displays as a success or failure message. You can use your profile when you issue commands in the `zftp` command group.

Note: There is an option named `--secure-ftp` that is set to `true` by default. If FTPS (FTP over SSL) is not enabled in z/OS FTP service, we recommend using `--secure-ftp false`. FTPS is not equivalent to SFTP (FTP over SSH).

Note: For more information about the syntax, actions, and options, for a profiles create command, open Zowe CLI and issue the following command:

```
zowe profiles create zftp -h
```

IBM® IMS™ Plug-in for Zowe CLI
The IBM IMS Plug-in for Zowe CLI lets you extend Zowe CLI such that it can interact with IMS resources (regions, programs and transactions). You can use the plug-in to start, stop, and query regions and start, stop, query, and update programs and transactions.

Note: For more information about IMS, see IBM Information Management System (IMS) on the IBM Knowledge Center.

[]
Use cases
As an application developer or DevOps administrator, you can use IBM IMS Plug-in for Zowe CLI to perform the following tasks:

- Refresh IMS transactions, programs, and dependent IMS regions.
- Deploy application code into IMS production or test systems.
- Write scripts to automate IMS actions that you traditionally perform using ISPF editors, TSO, and SPOC.

Commands
For detailed documentation on commands, actions, and options available in this plug-in, see our Web Help. It is available for download in three formats: a PDF document, an interactive online version, and a ZIP file containing the HTML for the online version.

- Browse Online
- Download (ZIP)
- Download (PDF)

Software requirements
Before you install the plug-in, meet the software requirements in Software requirements for Zowe CLI plug-ins on page 180.

Installing
Use one of the following methods to install or update the plug-in:

- Installing plug-ins from an online registry on page 182
- Installing plug-ins from a local package on page 182

Creating user profiles
You can set up an ims profile to retain your credentials, host, and port name. You can create multiple profiles and switch between them as needed. Issue the following command to create an ims profile:

```
zowe profiles create ims-profile <profileName> --host <hostname> --port <portnumber> --ims-connect-host <ims-hostname> --ims-connect-port <ims-portnumber> --user <username> --password <password>```

Example: Setting up an IMS profile
The following example creates an ims profile named 'ims123' to connect to IMS APIs at host zos123 and port 1490. The name of the IMS plex in this example is 'PLEX1' and the IMS region we want to communicate with has a host of zos124 and a port of 1491:

```
zowe profiles create ims-profile ims123 --host zos123 --port 1490 --user ibmuser --password myp4ss --plex PLEX1 --ich zos124 --icp 1491
```

Note: For more information, issue the command `zowe profiles create ims-profile --help`.

IBM® MQ Plug-in for Zowe CLI
The IBM MQ Plug-in for Zowe CLI lets you issue MQSC commands to a queue manager. MQSC commands let you perform administration tasks. For example, you can define, alter, or delete a local queue object.

Note: For more information about MQSC commands and the corresponding syntax, see MQSC commands on the IBM Knowledge Center.
Use cases

You can use the plug-in to execute MQSC Commands. With MQSC commands you can manage queue manager objects (including the queue manager itself), queues, process definitions, channels, client connection channels, listeners, services, namelists, clusters, and authentication information objects.

Using IBM MQ plug-in commands

For detailed documentation on commands, actions, and options available in this plug-in, see our Web Help. It is available for download in three formats: a PDF document, an interactive online version, and a ZIP file containing the HTML for the online version.

- Browse Online
- Download (ZIP)
- Download (PDF)

Software requirements

Before you install the plug-in, meet the software requirements in Software requirements for Zowe CLI plug-ins on page 180.

Installing

Use one of the following methods to install or update the plug-in:

- Installing plug-ins from an online registry on page 182
- Installing plug-ins from a local package on page 182

Creating a user profile

You can create an mq user profile to avoid typing your connection details on every command. An mq profile contains the host, port, username, and password for the MQ Rest API server of your choice. You can create multiple profiles and switch between them as needed.

Follow these steps:

1. Create an mq profile:

   ```bash
   zowe profiles create mq-profile <profileName> --host <hostname> --port <portnumber> --user <username> --password <password>
   ```

   The result of the command displays as a success or failure message. You can use your profile when you issue commands in the mq command group.

   Tip: For more information about the syntax, actions, and options, for a profiles create command, open Zowe CLI and issue the following command:

   ```bash
   zowe profiles create mq-profile -h
   ```

Secure Credential Store Plug-in for Zowe CLI

The Secure Credential Store (SCS) Plug-in for Zowe CLI lets you store your credentials securely in the credential manager of your operating system. The plug-in invokes a native Node module, keytar, that manages user IDs and passwords in a credential manager.

- Use Cases on page 192
- Commands on page 192
- Software requirements on page 192
- Installing on page 192
- Using on page 192
Use Cases
Zowe CLI stores credentials (mainframe username and password) in plaintext on your computer by default. You can use the SCS plug-in to store credentials more securely and prevent your credentials from being compromised as a result of a malware attack or unlawful actions by others.

Commands
For detailed command, actions, and option documentation for this plug-in, see our Web Help (available online or as PDF or ZIP):

•  Browse Online
•  Download (ZIP)
•  Download (PDF)

Software requirements
Before you install the plug-in, meet the software requirements in Software requirements for Zowe CLI plug-ins on page 180.

Installing
Use one of the following methods to install or update the plug-in:

•  Installing plug-ins from an online registry on page 182
•  Installing plug-ins from a local package on page 182

Note: Existing user profiles are not automatically updated to securely store credentials.

Using
The plug-in introduces a new command group, zowe scs, that lets you update existing user profiles and enable/disable the plug-in.

Securing your credentials
User profiles that you create after installing the plug-in will automatically store your credentials securely.

To secure credentials in existing user profiles (profiles that you created prior to installing the SCS plug-in), issue the following command:

```
zowe scs update
```

Profiles are updated with secured credentials.

Example: Secure credentials
The following is an example of securely stored credentials in a user profile configuration file:

```
type: zosmf
host: test
port: 1234
user: 'managed by @zowe/secure-credential-store-for-zowe-cli'
password: 'managed by @zowe/secure-credential-store-for-zowe-cli'
rejectUnauthorized: false
```

Example: Default credential management
The following is an example of credentials that are stored with the default credential manager:

```
type: zosmf
host: test
port: 1234
user: USERNAME
password: PASSWORD
```
Deactivating the plug-in

If you do not want to use the SCS Plug-in for Zowe CLI, choose one of the following methods to deactivate the plug-in:

**Uninstall the Plug-in**

Issue the `zowe plugins uninstall @zowe/secure-credential-store-for-zowe-cli` command to delete the plug-in from your computer.

When you uninstall the plug-in, existing profiles become invalid and you must recreate them. For more information, see Create CLI Profiles.

**Reset the Configuration of Credential Manager**

Issue the `zowe config reset CredentialManager` command to reset the value of the credential manager configuration to default, which deactivates the plug-in.

Zowe Explorer Extension for VSCode

The Zowe Explorer extension for Visual Studio Code (VSCode) lets you interact with data sets, USS files and jobs that are stored on z/OS mainframe. Install the extension directly to VSCode to enable the extension within the GUI. For some users, working with data sets and USS files from VSC can be more convenient than using 3270 emulators, and complements your Zowe CLI experience.

**Note:** The primary documentation for the Zowe Explorer is available on the Visual Studio Code Marketplace. This article is a high-level overview of the extension.

- **Use-Cases** on page 193
- **Software requirements** on page 193
- **Installing** on page 193
- **Working with user profiles** on page 194
- **Enabling Secure Credential Store** on page 194

**Use-Cases**

As a developer, you can use Zowe Explorer to perform the following tasks.

- View, rename, copy, and filter mainframe data sets, USS files, and jobs.
- Create download, edit, upload, and delete PDS and PDS members.
- Create, edit, and delete Zowe CLI compatible `zosmf` profiles.
- Switch between Zowe CLI `zosmf` profiles to quickly target different mainframe systems.
- Use the Secure Credential Store plug-in to store your credentials securely in the settings.
- Submit jobs.

**Software requirements**

Before you use the extension, meet the following software requirements on your computer:

- Get access to z/OSMF.
- Install Node.js v8.0 or later.
- Install VSCode.
- Create one Zowe CLI `zosmf` profile so that the extension can communicate with the mainframe.

**Note:** You might use an existing Zowe CLI `zosmf` profile that was created with the Zowe CLI v.2.0.0 or later.

**Installing**

1. Address **Software requirements** on page 193.
2. Open VSCode. Navigate to the **Extensions** tab on the left side of the UI.
3. Click the green **Install** button to install the extension.
4. Restart VSCode.

The extension is now installed and available for use.

**Tip:** For information about how to install the extension from a **VSIX** file and run system tests on the extension, see the Developer **README** file in the Zowe VSCode extension GitHub repository.

You can also watch the following videos to learn how to get started with Zowe Explorer, and work with data sets.

**Working with user profiles**

You must have a profile before you can use the extension. You can set up a **zosmf** profile to retain your credentials, host, and port name. In addition, you can create multiple profiles and use them simultaneously.

**Follow these steps:**

1. Navigate to the explorer tree.
2. Click the + button next to the **DATA SETS**, **USS** or **JOBS** bar.
   - **Note:** If you already have a profile, select it from the drop-down menu.
3. Select the **Create a New Connection to Z/OS** option.
   - **Note:** When you create a new profile, user name and password fields are optional. However, the system will prompt you to specify your credentials when you use the new profile for the first time.
4. Follow the instructions, and enter all required information to complete the profile creation.

The extension also enables you to hide a profile from the explorer tree, and permanently delete a profile. When you delete your profile permanently, the extension erases the profile from the `.zowe` folder. To hide or delete a profile, right-click the profile and choose the corresponding option from the options list.

**Enabling Secure Credential Store**

You can now use Secure Credential Store plug-in for Zowe CLI in the Zowe Explorer extension. Secure Credentials Store plug-in lets you store your credentials securely. For more information, see **Secure Credential Store Plug-in for Zowe Explorer**.
Chapter 3

Extending

Topics:

- Extending Zowe
- Developing for Zowe CLI
- Developing for API Mediation Layer
- Developing for Zowe Application Framework
- Zowe lifecycle
- Zowe Conformance Program
Extending Zowe

Zowe was designed to be an extensible tools platform. You can extend it in several ways to meet your needs or distribute the plug-ins to users who have already installed Zowe and want to introduce new functionality to it.

One of the goals of Zowe is to give users a consistent user experience, common functionality, and interoperability when using Zowe that includes the base set of Zowe core functions and plug-ins that are built outside the Zowe community. The Zowe Conformance Program provides a set of criteria to help with this. When followed, it also gives plug-in providers confidence that their software remains functional through Zowe releases. For more information, see Zowe Conformance Program on page 286.

You can extend Zowe in the following ways:

- Extending the Zowe Command Line Interface.
- Adding a REST API service to the API Mediation Layer.
- Adding a plug-in to the Zowe Desktop.

Extending the Zowe Command Line Interface

Command Line Interface extensions are able to provide new commands through their own plug-in, see Developing a new plug-in on page 205. There is a sample extension plug-in that is provided together with a tutorial, see Installing the sample plug-in on page 199.

The command line interface is built using Node.js and is typically run on a machine other than z/OS, such as a PC where it can be driven through a Terminal or command prompt, or on an automation machine such as a DevOps pipeline orchestrator. The API Mediation Layer and Zowe Desktop run on z/OS. Support for running the API Mediation Layer and Zowe Desktop off platform might come in a future release of Zowe. To understand the architecture of Zowe, see Zowe architecture on page 13.

Adding a REST API service to the API Mediation Layer

The API Mediation Layer includes an API gateway that acts as a reverse proxy server through which API requests can be routed from clients on its northbound edge to z/OS servers on its southbound edge. The API gateway is extensible so you can add REST APIs for z/OS servers to its list of services. For information about how to onboard REST APIs, see Onboarding Overview on page 211.

To register a z/OS server with the API Mediation layer, there are two techniques:

- Dynamic API registration on page 196
- Static API registration on page 197

Dynamic API registration

The API Gateway can be called by the server that wants to register their REST APIs through a set of API calls to the API Gateway itself. To do this, the z/OS server needs to know where the API Gateway is and make the API calls to register or unregister itself. This knowledge can either be within the z/OS server itself, or more typically is done by introducing a micro service whose task is to register to the API Mediation Layer on behalf of an existing z/OS Service and act as a registration broker. The coding pattern for the micro service is to create a Java Spring Boot server. For more information, see Onboarding a Spring Boot based REST API Service. This is a bottom up registration, where the z/OS service beneath the API Mediation Layer is calling up into it to say it is ready to receive API requests as well as information for how it should be rendered on the API catalog.

The Zowe z/OS started task ZWESVSTC that launches the Zowe address spaces allows for extra USS ‘microservices’ to be lifecycled with it, so that they are started together with Zowe and ended when Zowe started task is stopped. For more information, see Zowe lifecycle on page 284. This can be used, for example, to start and stop a dynamic APIML Spring Boot micro service that provides its own APIs or acts as a broker to register APIs on behalf of an existing z/OS server.
Static API registration

Instead of having the API service calling up to the API Mediation Layer, it is possible to tell the API Mediation
Layer about an API service by giving it a static file with details of the z/OS API service. This is referred to in the
documentation as being able to onboard without code changes, because there is no need to modify the existing API
service to have it call up to the API Mediation Layer, or introduce a Spring Boot micro service to do this on its behalf.
For more information, see Onboard a REST API without code changes required on page 226.

Adding a plug-in to the Zowe Desktop

The Zowe Desktop allows a user to interact with z/OS applications through a web browser. It is served by the Zowe
Application Framework Server on z/OS, also known as Z Lightweight User Experience (ZLUX). The Zowe desktop
comes with a set of default applications. You can extend it to add new applications. For more information, see
Overview on page 242.

The Zowe Desktop is an angular application that allows native plug-ins to be built that enjoy a high level of
interoperability with other desktop components. The React JavaScript toolkit is also supported. In addition, an
existing web application can be included in the Zowe Desktop using an iframe.

• iframe
  See Sample Iframe App on page 243.
• Angular App
  See Sample Angular App on page 243.
• React App
  See Sample React App on page 243.

Lifecycling extensions as Zowe address spaces

Zowe is run under the started task ZWESVSTC that brings up its address spaces. It is possible to introduce a new
micro service to be started and stopped with the Zowe stated task. For more information, see Zowe lifecycle on page
284.

Developing for Zowe CLI

Developing for Zowe CLI

You can extend Zowe™ CLI by developing plug-ins and contributing code to the base Zowe CLI or existing plug-ins.

How can I contribute?

You can contribute to Zowe CLI in the following ways:
1. Add new commands, options, or other improvements to the base CLI.
2. Develop a plug-in that users can install to Zowe CLI.

You might want to contribute to Zowe CLI to accomplish the following:
• Provide new scriptable functionality for yourself, your organization, or to a broader community.
• Make use of Zowe CLI infrastructure (profiles and programmatic APIs).
• Participate in the Zowe CLI community space.

Getting started

If you want to start working with the code immediately, check out the Zowe CLI core repository and the contribution
guidelines. The zowe-cli-sample-plugin GitHub repository is a sample plug-in that adheres to the guidelines for
contributing to Zowe CLI projects.
Tutorials

Follow these tutorials to get started working with the sample plug-in:

1. **Setting up your development environment** on page 198 - Clone the project and prepare your local environment.
2. **Installing the sample plug-in** on page 199 - Install the sample plug-in to Zowe CLI and run as-is.
3. **Extending a plug-in** on page 202 - Extend the sample plug-in with a new by creating a programmatic API, definition, and handler.
4. **Developing a new plug-in** on page 205 - Create a new CLI plug-in that uses Zowe CLI programmatic APIs and a diff package to compare two data sets.
5. **Implementing profiles in a plug-in** on page 210 - Implement user profiles with the plug-in.

Plug-in Development Overview

At a high level, a plug-in must have **imperative-framework configuration** (sample here). This configuration is discovered by **imperative-framework** through the **package.json imperative** key.

A Zowe CLI plug-in will minimally contain the following:

1. **Programmatic API** - Node.js programmatic APIs to be called by your handler or other Node.js applications.
2. **Command definition** - The syntax definition for your command.
3. **Handler implementation** - To invoke your programmatic API to display information in the format that you defined in the definition.

The following guidelines and documentation will assist you during development:

**Imperative CLI Framework Documentation**

**Imperative CLI Framework documentation** is a key source of information to learn about the features of Imperative CLI Framework (the code framework that you use to build plug-ins for Zowe CLI). Refer to these supplementary documents during development to learn about specific features such as:

- Auto-generated help
- JSON responses
- User profiles
- Logging, progress bars, experimental commands, and more!

**Contribution Guidelines**

The Zowe CLI contribution guidelines contain standards and conventions for developing Zowe CLI plug-ins. The guidelines contain critical information about working with the code, running/writing/maintaining automated tests, developing consistent syntax in your plug-in, and ensuring that your plug-in integrates with Zowe CLI properly:

<table>
<thead>
<tr>
<th>For more information about ...</th>
<th>See:</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

**Setting up your development environment**

Before you follow the development tutorials for creating a Zowe™ CLI plug-in, follow these steps to set up your environment.
Prequisites

Methods to install Zowe CLI on page 116.

Initial setup

To create your development space, you will clone and build `zowe-cli-sample-plugin` from source.

Before you clone the repository, create a local development folder named `zowe-tutorial`. You will clone and build all projects in this folder.

Branches

There are two branches in the repository that correspond to different Zowe CLI versions. You can develop two branches of your plug-in so that users can install your plug-in into `@latest` or `@zowe-v1-lts` CLI. Developing for both versions will let you take advantage of new core features quickly and expose your plug-in to a wider range of users.

The `master` branch of Sample Plug-in is compatible with the `@zowe-v1-lts` version of core CLI (Zowe LTS release).

The `master` branch of Sample Plug-in is also compatible with the `@latest` version of core CLI (Zowe Active Development release) at this time.

For more information about the versioning scheme, see Maintaner Versioning in the Zowe CLI repository.

Clone zowe-cli-sample-plugin and build from source

Clone the repository into your development folder to match the following structure:

```
zowe-tutorial
  ### zowe-cli-sample-plugin
```

Follow these steps:

1. cd to your `zowe-tutorial` folder.
2. git clone https://github.com/zowe/zowe-cli-sample-plugin
3. cd to your `zowe-cli-sample-plugin` folder.
4. git checkout master
5. npm install
6. npm run build

(Optional) Run the automated tests

We recommend running automated tests on all code changes. Follow these steps:

1. cd to the `__tests__/__resources__/properties` folder.
2. Copy `example_properties.yaml` to `custom_properties.yaml`.
3. Edit the properties within `custom_properties.yaml` to contain valid system information for your site.
4. cd to your `zowe-cli-sample-plugin` folder
5. npm run test

Next steps

After you complete your setup, follow the Installing the sample plug-in on page 199 tutorial to install this sample plug-in to Zowe CLI.

Installing the sample plug-in

Before you begin, Setting up your development environment on page 198 your local environment to install a plug-in.
Overview

This tutorial covers installing and running this bundled Zowe™ CLI plugin as-is (without modification), which will display your current directory contents.

The plug-in adds a command to the CLI that lists the contents of a directory on your computer.

Installing the sample plug-in to Zowe CLI

To begin, cd into your zowe-tutorial folder.

Issue the following commands to install the sample plug-in to Zowe CLI:

```bash
zowe plugins install ./zowe-cli-sample-plugin
```

Viewing the installed plug-in

Issue `zowe --help` in the command line to return information for the installed `zowe-cli-sample` command group:
Figure 2: Installed Sample Plugin

Using the installed plug-in

To use the plug-in functionality, issue: `zowe zowe-cli-sample list directory-contents`:
To run automated tests against the plug-in, cd into your zowe-tutorial/zowe-cli-sample-plugin folder. Issue the following command:

- npm run test

**Next steps**

You successfully installed a plug-in to Zowe CLI! Next, try the Extending a plug-in on page 202 tutorial to learn about developing new commands for this plug-in.

**Extending a plug-in**

Before you begin, be sure to complete the Installing the sample plug-in on page 199 tutorial.

**Overview**

This tutorial demonstrates how to extend the plug-in that is bundled with this sample by:

1. Creating a new programmatic API
2. Creating a new command definition
3. Creating a new handler

We'll do this by using @zowe/imperative infrastructure to surface REST API data on our Zowe™ CLI plug-in. Specifically, we're going to show data from this URI by Typicode. Typicode serves sample REST JSON data for testing purposes.

At the end of this tutorial, you will be able to use a new command from the Zowe CLI interface: zowe zowe-cli-sample list typicode-todos

Completed source for this tutorial can be found on the typicode-todos branch of the zowe-cli-sample-plugin repository.
Creating a Typescript interface for the Typicode response data

First, we'll create a Typescript interface to map the response data from a server.

Within `zowe-cli-sample-plugin/src/api`, create a folder named `doc` to contain our interface (sometimes referred to as a “document” or “doc”). Within the `doc` folder, create a file named `ITodo.ts`.

The `ITodo.ts` file will contain the following:

```typescript
export interface ITodo {
    userId: number;
    id: number;
    title: string;
    completed: boolean;
}
```

Creating a programmatic API

Next, we'll create a Node.js API that our command handler uses. This API can also be used in any Node.js application, because these Node.js APIs make use of REST APIs, Node.js APIs, other NPM packages, or custom logic to provide higher level functions than are served by any single API.

Adjacent to the existing file named `zowe-cli-sample-plugin/src/api/Files.ts`, create a file `Typicode.ts`. `Typicode.ts` should contain the following:

```typescript
import { ITodo } from './doc/ITodo';
import { RestClient, AbstractSession, ImperativeExpect, Logger } from '@zowe/imperative';

export class Typicode {
    public static readonly TODO_URI = '/todos';

    public static getTodos(session: AbstractSession): Promise<ITodo[]> {
        Logger.getAppLogger().trace('Typicode.getTodos() called');
        return RestClient.getExpectJSON<ITodo[]>(session, Typicode.TODO_URI);
    }

    public static getTodo(session: AbstractSession, id: number): Promise<ITodo> {
        Logger.getAppLogger().trace('Typicode.getTodos() called with id ' + id);
        ImperativeExpect.toNotBeNullOrUndefined(id, 'id must be provided');
        const resource = Typicode.TODO_URI + '/' + id;
        return RestClient.getExpectJSON<ITodo>(session, resource);
    }
}
```

The `Typicode` class provides two programmatic APIs, `getTodos` and `getTodo`, to get an array of `ITodo` objects or a specific `ITodo` respectively. The Node.js APIs use `@zowe/imperative` infrastructure to provide logging, parameter validation, and to call a REST API. See the Imperative CLI Framework documentation for more information.

Exporting interface and programmatic API for other Node.js applications

Update `zowe-cli-sample-plugin/src/index.ts` to contain the following:

```typescript
export * from './api/doc/ITodo';
export * from './api/Typicode';
```
A sample invocation of your API might look similar to the following, if it were used by a separate, standalone Node.js application:

```javascript
import { Typicode } from "@zowe/zowe-cli-sample-plugin";
import { Session, Imperative } from "@zowe/imperative";
import { inspect } from "util";

const session = new Session({ hostname: "jsonplaceholder.typicode.com"});

(async () => {
  const firstTodo = await Typicode.getTodo(session, 1);
  Imperative.console.debug("First todo was: " + inspect(firstTodo));
})();
```

Checkpoint

Issue `npm run build` to verify a clean compilation and confirm that no lint errors are present. At this point in this tutorial, you have a programmatic API that will be used by your handler or another Node.js application. Next you'll define the command syntax for the command that will use your programmatic Node.js APIs.

Defining command syntax

Within Zowe CLI, the full command that we want to create is `zowe zowe-cli-sample list typicode-todos`. Navigate to `zowe-cli-sample-plugin/src/cli/list` and create a folder `typicode-todos`. Within this folder, create `TypicodeTodos.definition.ts`. Its content should be as follows:

```typescript
import { ICommandDefinition } from "@zowe/imperative";
export const TypicodeTodosDefinition: ICommandDefinition = {
  name: "typicode-todos",
  aliases: ["td"],
  summary: "Lists typicode todos",
  description: "List typicode REST sample data",
  type: "command",
  handler: __dirname + "/TypicodeTodos.handler",
  options: [
    {
      name: "id",
      description: "The todo to list",
      type: "number"
    }
  ]
};
```

This describes the syntax of your command.

Defining command handler

Also within the `typicode-todos` folder, create `TypicodeTodos.handler.ts`. Add the following code to the new file:

```typescript
import { ICommandHandler, IHandlerParameters, TextUtils, Session } from "@zowe/imperative";
import { Typicode } from "../../../api/Typicode";
export default class TypicodeTodosHandler implements ICommandHandler {
  public static readonly TYPICODE_HOST = "jsonplaceholder.typicode.com";
  public async process(params: IHandlerParameters): Promise<void> {
    const session = new Session({ hostname: TypicodeTodosHandler.TYPICODE_HOST});
    if (params.arguments.id) {
      const todo = await Typicode.getTodo(session, params.arguments.id);
      params.response.data.setObj(todo);
    }
  }
}
```
params.response.console.log(TextUtils.prettyJson(todo));
}
else {
    const todos = await Typicode.getTodos(session);
    params.response.data.setObj(todos);
    params.response.console.log(TextUtils.prettyJson(todos));
}
}

The if statement checks if a user provides an --id flag. If yes, we call getTodo. Otherwise, we call getTodos. If the Typicode API throws an error, the @zowe/imperative infrastructure will automatically surface this.

Defining command to list group

Within the file zowe-cli-sample-plugin/src/cli/list/List.definition.ts, add the following code below other import statements near the top of the file:

```typescript
import { TypicodeTodosDefinition } from './typicode-todos/
    TypicodeTodos.definition';
```

Then add TypicodeTodosDefinition to the children array. For example:

```javascript
children: [DirectoryContentsDefinition, TypicodeTodosDefinition]
```

Checkpoint

Issue npm run build to verify a clean compilation and confirm that no lint errors are present. You now have a handler, definition, and your command has been defined to the list group of the command.

Using the installed plug-in

Issue the command: zowe zowe-cli-sample list typicode-todos

Refer to zowe zowe-cli-sample list typicode-todos --help for more information about your command and to see how text in the command definition is presented to the end user. You can also see how to use your optional --id flag:

```
$ zowe zowe-cli-sample list typicode-todos --id 4
userId: 1
id: 4
title: et porro tempora
completed: true
```

Summary

You extended an existing Zowe CLI plug-in by introducing a Node.js programmatic API, and you created a command definition with a handler. For an official plugin, you would also add JSDoc to your code and create automated tests.

Next steps

Try the Developing a new plug-in on page 205 tutorial next to create a new plug-in for Zowe CLI.

Developing a new plug-in

Before you begin this tutorial, complete the Extending a plug-in on page 202 tutorial.
Overview

This tutorial demonstrates how to create a brand new Zowe™ CLI plug-in that uses Zowe CLI Node.js programmatic APIs.

At the end of this tutorial, you will have created a data set diff utility plug-in for Zowe CLI, from which you can pipe your plugin's output to a third-party utility for a side-by-side diff of data set member contents.

Completed source for this tutorial can be found on the develop-a-plugin branch of the zowe-cli-sample-plugin repository.

Cloning the sample plug-in source

Clone the sample repo, delete the irrelevant source, and create a brand new plug-in. Follow these steps:

1. `cd` into your zowe-tutorial folder
2. `git clone https://github.com/zowe/zowe-cli-sample-plugin files-util`
3. `cd files-util`
4. Delete the `.git` (hidden) folder.
5. Delete all content within the `src/api`, `src/cli`, and `docs` folders.
6. Delete all content within the `__tests__/__system__/api`, `__tests__/__system__/cli`, `__tests__/api`, and `__tests__/cli` folders
7. `git init`
8. `git add .`
9. `git commit -m "initial"`

Changing package.json

Use a unique npm name for your plugin. Change package.json name field as follows:

```json
"name": "@zowe/files-util",
```

Issue the command `npm install` against the local repository.

Adjusting Imperative CLI Framework configuration

Change `imperative.ts` to contain the following:

```typescript
import { IImperativeConfig } from '@zowe/imperative';

const config: IImperativeConfig = {
  commandModuleGlobs: ['**/cli/!*.*.definition!(.d).*s'],
  rootCommandDescription: "Files utility plugin for Zowe CLI",
  envVariablePrefix: "FILES_UTIL_PLUGIN",
};
```
| Extending | 207

defaultHome: "~/.files_util_plugin",
productDisplayName: "Files Util Plugin",
name: "files-util"
};
export = config;
Here we adjusted the description and other fields in the imperative JSON configuration to be relevant to this
plug-in.
Adding third-party packages
We'll use the following packages to create a programmatic API:
•
•

npm install --save diff
npm install -D @types/diff

Creating a Node.js programmatic API
In files-util/src/api, create a file named DataSetDiff.ts. The content of DataSetDiff.ts should
be the following:
import
import
import
import

{
{
*
{

AbstractSession } from "@zowe/imperative";
Download, IDownloadOptions, IZosFilesResponse } from "@zowe/cli";
as diff from "diff";
readFileSync } from "fs";

export class DataSetDiff {
public static async diff(session: AbstractSession, oldDataSet: string,
newDataSet: string) {
let error;
let response: IZosFilesResponse;
const options: IDownloadOptions = {
extension: "dat",
};
try {
response = await Download.dataSet(session, oldDataSet, options);
} catch (err) {
error = "oldDataSet: " + err;
throw error;
}
try {
response = await Download.dataSet(session, newDataSet, options);
} catch (err) {
error = "newDataSet: " + err;
throw error;
}
const regex = /\.|\(/gi; // Replace . and ( with /
const regex2 = /\)/gi;
// Replace ) with .
// convert the old data set name to use as a path/file
let file = oldDataSet.replace(regex, "/");
file = file.replace(regex2, ".") + "dat";
// Load the downloaded contents of 'oldDataSet'
const oldContent = readFileSync(`${file}`).toString();
// convert the new data set name to use as a path/file
file = newDataSet.replace(regex, "/");


Extending

file = file.replace(regex2, ".") + "dat";
// Load the downloaded contents of 'oldDataSet'
const newContent = readFileSync(`${file}`).toString();

return diff.createTwoFilesPatch(oldDataSet, newDataSet, oldContent, newContent, "Old", "New");
}

Exporting your API

In files-util/src, change index.ts to contain the following:

```typescript
export * from "./api/DataSetDiff";
```

Checkpoint

At this point, you should be able to rebuild the plug-in without errors via npm run build. You included third party dependencies, created a programmatic API, and customized this new plug-in project. Next, you'll define the command to invoke your programmatic API.

Defining commands

In files-util/src/cli, create a folder named diff. Within the diff folder, create a file Diff.definition.ts. Its content should be as follows:

```typescript
import { ICommandDefinition } from '@zowe/imperative';
import { DataSetsDefinition } from './data-sets/DataSets.definition';
const IssueDefinition: ICommandDefinition = {
    name: "diff",
    summary: "Diff two data sets content",
    description: "Uses open source diff packages to diff two data sets content",
    type: "group",
    children: [DataSetsDefinition]
};

export = IssueDefinition;
```

Also within the diff folder, create a folder named data-sets. Within the data-sets folder create DataSets.definition.ts and DataSets.handler.ts.

DataSets.definition.ts should contain:

```typescript
import { ICommandDefinition } from '@zowe/imperative';

export const DataSetsDefinition: ICommandDefinition = {
    name: "data-sets",
    aliases: ["ds"],
    summary: "data sets to diff",
    description: "diff the first data set with the second",
    type: "command",
    handler: __dirname + "/DataSets.handler",
    positionals: [
        {
            name: "oldDataSet",
            description: "The old data set",
            type: "string"
        },
        {
            name: "newDataSet",
            description: "The new data set",
            type: "string"
        }
    ]
};
```
DataSets.handler.ts should contain the following:

```javascript
import { ICommandHandler, IHandlerParameters, TextUtils, Session } from "@zowe/imperative";
import { DataSetDiff } from "../../../api/DataSetDiff";

export default class DataSetsDiffHandler implements ICommandHandler {
    public async process(params: IHandlerParameters): Promise<void> {
        const profile = params.profiles.get("zosmf");
        const session = new Session({
            type: "basic",
            hostname: profile.host,
            port: profile.port,
            user: profile.user,
            password: profile.pass,
            base64EncodedAuth: profile.auth,
            rejectUnauthorized: profile.rejectUnauthorized,
        });
        const resp = await DataSetDiff.diff(session,
            params.arguments.oldDataSet, params.arguments.newDataSet);
        params.response.console.log(resp);
    }
}
```

**Trying your command**

Be sure to build your plug-in via `npm run build`.

Install your plug-in into Zowe CLI via `zowe plugins install`.

Issue the following command. Replace the data set names with valid mainframe data set names on your system:

```
$ zowe files-util diff data-sets "<old_dataset>" "<new_dataset>"
```

The raw diff output is displayed as a command response:

```
$ zowe files-util diff data-sets "<old_dataset>" "<new_dataset>
@@ -1,2 +1,2 @@
-<old_dataset>
+<new_dataset>
```

**Bringing together new tools!**

The advantage of Zowe CLI and of the CLI approach in mainframe development is that it allows for combining different developer tools for new and interesting uses.
**diff2html** is a free tool to generate HTML side-by-side diffs to help see actual differences in diff output.

Install the **diff2html** CLI via `npm install -g diff2html-cli`. Then, pipe your Zowe CL plugin's output into **diff2html** to generate diff HTML and launch a web browser that contains the content in the screen shot at the **Overview** on page 206.

- `zowe files-util diff data-sets "kelda16.work.jcl(iefbr14)"  
  "kelda16.work.jcl(iefbr15)" | diff2html -i stdin`

**Next steps**

Try the **Implementing profiles in a plug-in** on page 210 tutorial to learn about using profiles with your plug-in.

**Implementing profiles in a plug-in**

You can use this profile template to create a profile for your product.

The profile definition is placed in the **imperative.ts** file.

**someproduct** will be the profile name that you might require on various commands to have credentials loaded from a secure credential manager and retain host/port information (so that you can easily swap to different servers) from the CLI.

By default, if your plug-in is installed into Zowe™ CLI that contains a profile definition like this, commands will automatically be created under **zowe profiles** ... to create, validate, set default, list, etc... for your profile.

```
profiles: [

    {
        type: "someproduct",
        schema: {
            type: "object",
            title: "Configuration profile for SOME PRODUCT",
            description: "Configuration profile for SOME PRODUCT",
            properties: {
                host: {
                    type: "string",
                    optionDefinition: {
                        type: "string",
                        name: "host",
                        alias: ["H"],
                        required: true,
                        description: "Host name of your SOME PRODUCT REST API server"
                    }
                },
                port: {
                    type: "number",
                    optionDefinition: {
                        type: "number",
                        name: "port",
                        alias: ["P"],
                        required: true,
                        description: "Port number of your SOME PRODUCT REST API server"
                    }
                },
                user: {
                    type: "string",
                    optionDefinition: {
                        type: "string",
                        name: "user",
                        alias: ["u"],
                        required: true,
                        description: "User name to authenticate to your SOME PRODUCT REST API server"
                    }
                }
            }
        }
    }
```
Next steps

If you completed all previous tutorials, you now understand the basics of extending and developing plug-ins for Zowe CLI. Next, we recommend reviewing the project Contribution Guidelines on page 198 and Imperative CLI Framework Documentation on page 198 to learn more.

Developing for API Mediation Layer

Onboarding Overview

As an API developer, you can onboard a REST API service to the Zowe™ API Mediation Layer (API ML). Onboarding your REST service to the Zowe™ API Mediation Layer will make your service discoverable by the API ML Discovery Service, enable routing through the API Gateway, and make service information and API documentation available through the API Catalog.

The specific method you use to onboard a REST API to the API ML depends on the programming language or framework used to build your REST service.

This Onboarding Overview article addresses the following topics:

- Prerequisites on page 211
- Service Onboarding Guides on page 212 to onboard your REST service with the API ML
- Validating successful onboarding
- Using the Sample REST API Service on page 214 to learn how to onboard a REST service to the API ML

Prerequisites

Meet the following prerequisites before you onboard your service:
• Running instance of Zowe
  
  **Note:** For Onboard a REST API without code changes required on page 226, access to Zowe runtime is required to create the static service definition.

• A certificate that is trusted by Zowe
  
  Zowe uses secured communication over TLSv1.2. As such, the protocol version and the certificate is required. For more information, see API Mediation Layer security setup.

• A REST API-enabled service that you want to onboard
  
  If you do not have a specific REST API service, you can use the sample service.

  Your service should be documented in a valid OpenApi 2.0/3.0 Swagger JSON format.

• Access to the Zowe artifactory
  
  **Repository URL:** https://zowe.jfrog.io/zowe/libs-release

• Either the Gradle or Maven build automation system

**Service Onboarding Guides**

Services can be updated to support the API Mediation Layer natively by updating the service code. Use one of the following guides to onboard your REST service to the Zowe API Mediation Layer:

**Recommended guides for services using Java**

• Onboard a REST API service with the Plain Java Enabler (PJE)
• Onboard a Spring Boot based REST API Service

**Guides for Static Onboarding and Direct Call Onboarding**

Use one of the following guides if your service is not built with Java, or you do not want to change your codebase or use the previously mentioned libraries:

• Onboard a REST API without code changes required on page 226
• Onboarding a service with the Zowe API Meditation Layer without an onboarding enabler on page 219

**Documentation for legacy enablers**

For legacy enabler documentation (version 1.2 and lower), refer to the previous version of the documentation:

• Zowe Docs version 1.8.x

  **Note:** Enabler version 1.2 and previous versions are no longer supported.

  **Tip:** We recommend you use the enabler version 1.3 or higher to onboard your REST API service to the Zowe API Mediation Layer.

**Verify successful onboarding to the API ML**

Verifying that your service was successfully onboarded to the API ML can be done by ensuring service registration in the API ML Discovery Service or visibility of the service in the API ML Catalog.

**Verifying service discovery through Discovery Service**

Verify that your service is discovered by the Discovery Service with the following procedure.

**Follow these steps:**

1. Issue a HTTP GET request to the Discovery Service endpoint `/eureka/apps` to get service instance information:

   https://{zowe-hostname}:{discovery-service-port}/eureka/apps/{serviceId}

  **Note:** The endpoint is protected by client certificate verification. A valid trusted certificate must be provided with the HTTP GET request.
2. Check your service metadata.

Response example:

```xml
<application>
  <name>{serviceId}</name>
  <instanceId>{hostname}:{serviceId}:{port}</instanceId>
  <hostName>{hostname}</hostName>
  <app>{serviceId}</app>
  <ipAddr>{ipAddress}</ipAddr>
  <status>UP</status>
  <port enabled="false">{port}</port>
  <securePort enabled="true">{port}</securePort>
  <vipAddress>{serviceId}</vipAddress>
  <secureVipAddress>{serviceId}</secureVipAddress>
  <metadata>
    <apiml.service.description>Sample API service showing how to onboard the service</apiml.service.description>
    <apiml.routes.api__v1.gatewayUrl>api/v1</apiml.routes.api__v1.gatewayUrl>
    <apiml.routes.ws__v1.serviceUrl>/sampleclient/ws</apiml.routes.ws__v1.serviceUrl>
    <apiml.routes.ws__v1.gatewayUrl>ws/v1</apiml.routes.ws__v1.gatewayUrl>
    <apiml.routes.ui__v1.gatewayUrl>ui/v1</apiml.routes.ui__v1.gatewayUrl>
    <apiml.apiInfo.0.apiId>org.zowe.sampleclient</apiml.apiInfo.0.apiId>
    <apiml.apiInfo.0.gatewayUrl>api/v1</apiml.apiInfo.0.gatewayUrl>
    <apiml.apiInfo.0.documentationUrl>https://www.zowe.org</apiml.apiInfo.0.documentationUrl>
    <apiml.routes.ui__v1.serviceUrl>/sampleclient/api/v1</apiml.routes.ui__v1.serviceUrl>
    <apiml.apiInfo.0.swaggerUrl>https://hostname/sampleclient/api-doc</apiml.apiInfo.0.swaggerUrl>
  </metadata>
</application>
```

Tips:

- Ensure that addresses and user credentials for individual API ML components correspond to your target runtime environment.
- If you work with local installation of API ML and you use our dummy identity provider, enter user for both `username` and `password`. If API ML was installed by system administrators, ask them to provide you with actual addresses of API ML components and the respective user credentials.

**Verifying service discovery through the API Catalog**

Services may not be immediately visible in the API Catalog. We recommend you wait for 2 minutes as it may take a moment for your service to be visible in the Catalog. If your service still does not appear in the Catalog, ensure that your configuration settings are correct.

**Follow these steps:**
1. Check to see that your API service is displayed in the API Catalog UI, and that all information including API documentation is correct.
2. Ensure that you can access your API service endpoints through the Gateway.

**Sample REST API Service**

To demonstrate the concepts that apply to REST API services, we use an example of a Spring Boot REST API service. This example is used in the REST API onboarding guide Onboard a REST API without code changes required on page 226 (static onboarding).

You can build this service using instructions in the source code of the Spring Boot REST API service example.

The Sample REST API Service has a base URL. When you start this service on your computer, the service base URL is: http://localhost:8080.

**Note:** If a service is deployed to a web application server, the base URL of the service (application) has the following format: https://application-server-hostname:port/application-name.

This sample service provides one API that has the base path /v2, which is represented in the base URL of the API as http://localhost:8080/v2. In this base URL, /v2 is a qualifier of the base path that was chosen by the developer of this API. Each API has a base path depending on the particular implementation of the service.

This sample API has only one single endpoint:

- /pets/{id} - Find pet by ID.

This endpoint in the sample service returns information about a pet when the {id} is between 0 and 10. If {id} is greater than 0 or a non-integer, an error is returned. These are conditions set in the sample service.

**Tip:** Access http://localhost:8080/v2/pets/1 to see what this REST API endpoint does. You should get the following response:

```json
{
    "category": {
        "id": 2,
        "name": "Cats"
    },
    "id": 1,
    "name": "Cat 1",
    "photoUrls": [
        "url1",
        "url2"
    ],
    "status": "available",
    "tags": [
        {
            "id": 1,
            "name": "tag1"
        },
        {
            "id": 2,
            "name": "tag2"
        }
    ]
}
```

**Note:** The onboarding guides demonstrate how to add the Sample REST API Service to the API Mediation Layer to make the service available through the petstore service ID.

The following diagram shows the relations between the Sample REST API Service and its corresponding API, REST API endpoint, and API Gateway:
This sample service provides a Swagger document in JSON format at the following URL:

http://localhost:8080/v2/swagger.json

The Swagger document is used by the API Catalog to display API documentation.

**API Mediation Layer onboarding configuration**

This article describes the process of configuring a REST service to onboard with the Zowe API Mediation Layer using the API ML Plain Java Enabler. As a service developer, you can provide basic configuration of a service to onboard to the API ML. You can also externalize configuration parameters for subsequent customization by a systems administrator.

- Introduction on page 215
- Configuring a REST service for API ML onboarding on page 216
- Plain Java Enabler service onboarding API on page 217
  - Automatic initialization of the onboarding configuration by a single method call on page 217
  - Loading YAML configuration files on page 218
    - Loading a single YAML configuration file on page 218
    - Loading and merging two YAML configuration files on page 218

**Introduction**

The API ML Plain Java Enabler (PJE) is a library which helps to simplify the process of onboarding a REST service with the API ML. This article describes how to provide and externalize the Zowe API ML onboarding configuration of your REST service using the PJE.

**Note:** For more information about specific configuration parameters and their possible values, and the service registration process, see the specific documentation of the onboarding approach you are using for your project:
- Onboarding a service with the Zowe API Meditation Layer without an onboarding enabler on page 219
- Plain Java Enabler

The PJE is the most universal Zowe API ML enabler. This enabler uses only Java, and does not use advanced Inversion of Control (IoC) or Dependency Injection (DI) technologies. The PJE enables you to onboard any REST service implemented in Java, avoiding dependencies, versions collisions, unexpected application behavior, and unnecessarily large service executables.

Service developers provide onboarding configuration as part of the service source code. While this configuration is valid for the development system environment, it is likely to be different for an automated integration environment. Typically, system administrators need to deploy a service on multiple sites that have different system environments and requirements such as security.

The PJE supports both the service developer and the system administrator with the functionality of externalizing the service onboarding configuration.

The PJE provides a mechanism to load API ML onboarding service configuration from one or two YAML files.

**Configuring a REST service for API ML onboarding**

In most cases, the API ML Discovery Service, Gateway, and service endpoint addresses are not known at the time of building the service executables. Similarly, security material such as certificates, private/public keys, and their corresponding passwords depend on the specific deployment environment, and are not intended to be publicly accessible. Therefore, to provide a higher level of flexibility, the PJE implements routines to build service onboarding configuration by locating and loading one or two YAML file sources:

- **internal service-configuration.yml**
  The first configuration file is typically internal to the service deployment artifact. This file must be accessible on the service classpath. This file contains basic API ML configuration based on values known at development time. Usually, this basic API ML configuration is provided by the service developer and is located in the /resources folder of the Java project source tree. This file is usually found in the deployment artifacts under /WEB-INF/classes. The configuration contained in this file is provided by the service developer or builder. As such, it will not match every possible production environment and its corresponding requirements.

- **external or additional service-configuration.yml**
  The second configuration file is used to externalize the configuration. This file can be stored anywhere on the local file system, as long as that the service has access to that location. This file is provided by the service deployer/system administrator and contains the correct parameter values for the specific production environment.

At service start-up time, both YAML configuration files are merged, where the externalized configuration (if provided) has higher priority.

The values of parameters in both files can be rewritten by Java system properties or servlet context parameters that were defined during service installation/configuration, or at start-up time.

In the YAML file, standard rewriting placeholders for parameter values use the following format:

${apiml.parameter.key}

The actual values are taken from pairs defined as Java system properties or servlet context parameters. The system properties can be provided directly on a command line. The servlet context parameters can be provided in the service web.xml or in an external file.

The specific approach of how to provide the servlet context to the user service application depends on the application loading mechanism and the specific Java servlet container environment.

**Example:**

If the service is deployed in a Tomcat servlet container, you can configure the context by placing an XML file with the same name as the application deployment unit into _$CATALINA_BASE/conf/[enginename]/[hostname]/_

Other containers provide different mechanisms for the same purpose.
Plain Java Enabler service onboarding API

You can initialize your service onboarding configuration using different methods of the Plain Java Enabler class `ApiMediationServiceConfigReader`:

**Automatic initialization of the onboarding configuration by a single method call**

The following code block shows automatic initialization of the onboarding configuration by a single method call:

```java
public ApiMediationServiceConfig initializeAPIMLConfiguration(ServletContext context);
```

This method receives the `ServletContext` parameter, which holds a map of parameters that provide all necessary information for building the onboarding configuration. The following code block is an example of Java Servlet context configuration.

**Example:**

```xml
<Context>
  <Parameter name="apiml.config.location" value="/service-config.yml"/>
  <!-- Relative path to configuration file: -->
  <Parameter name="apiml.config.additional-location" value="../conf/Catalina/localhost/apiml-plugin-poc_plain-java-enabler.yml"/>
  <Parameter name="apiml.config.additional-location" value="/home/pin/bin/apache-tomcat-9.0.14/conf/Catalina/localhost/apiml-plugin-poc_plain-java-enabler.yml"/>
  <Parameter name="apiml.serviceId" value="discopin"/>
  <Parameter name="apiml.serviceIpAddress" value="127.0.0.2"/>
  <Parameter name="apiml.discoveryService.hostName" value="localhost"/>
  <Parameter name="apiml.discoveryService.port" value="10011"/>
  <Parameter name="apiml.ssl.enabled" value="true"/>
  <Parameter name="apiml.ssl.verifySslCertificatesOfServices" value="true"/>
  <Parameter name="apiml.ssl.keyPassword" value="password"/>
  <Parameter name="apiml.ssl.keystore.password" value="password"/>
  <Parameter name="apiml.ssl.truststore.password" value="password"/>
  <Parameter name="apiml.ssl.keystore" value="../keystore/localhost/localhost.truststore.p12"/>
  <Parameter name="apiml.ssl.truststore" value="../keystore/localhost/localhost.truststore.p12"/>
</Context>
```

Where the two parameters corresponding to the location of the configuration files are:

- `apiml.config.location`
  - This parameter describes the location of the basic configuration file.
- `apiml.config.additional-location`
  - This parameter describes the location of the external configuration file.

The method in this example uses the provided configuration file names in order to load them as YAML files into the internal Java configuration object of type `ApiMediationServiceConfig`.

The other context parameters with the `apiml` prefix are used to rewrite values of properties in the configuration files.
Loading YAML configuration files

YAML configuration files can be loaded either as a single YAML file, or by merging two YAML files. Use the loadConfiguration method described later in this article that corresponds to your service requirements.

After successfully loading a configuration file, the loading method loadConfiguration uses Java system properties to substitute corresponding configuration properties.

Loading a single YAML configuration file

To build your configuration from multiple sources, load a single configuration file, and then rewrite parameters as needed using values from another configuration source. See: Loading and merging two YAML configuration files described later in this article.

Use the following method to load a single YAML configuration file:

```java
public ApiMediationServiceConfig loadConfiguration(String configurationFileName);
```

This method receives a single String parameter and can be used to load an internal or an external configuration file.

Note: This method first attempts to load the configuration as a Java resource. If the file is not found, the method attempts to resolve the file name as an absolute. If the file name still cannot be found, this method attempts to resolve the file as a relative path. When the file is found, the method loads the contents of the file and maps them to internal data classes. After loading the configuration file, the method attempts to substitute/rewrite configuration property values with corresponding Java System properties.

Loading and merging two YAML configuration files

To load and merge two configuration files, use the following method:

```java
public ApiMediationServiceConfig loadConfiguration(String internalConfigurationFileName, String externalizedConfigurationFileName);
```

where:

- **String internalConfigurationFileName**
  references the basic configuration file name.

- **String externalizedConfigurationFileName**
  references the external configuration file name.

Note: The external configuration file takes precedence over the basic configuration file in order to match the target deployment environment. After loading and before merging, each configuration will be separately patched using Java System properties.

The following code block presents an example of how to load and merge onboarding configuration from YAML files.

Example:

```java
@Slf4j
public class ApiDiscoveryListener implements ServletContextListener {
    /**
     * @link ApiMediationClient instance used to register and unregister the service with API ML Discovery service.
     */
    private ApiMediationClient apiMediationClient;
    /**
     * Creates {@link ApiMediationServiceConfig}
     * Creates and initializes {@link ApiMediationClient} instance, which is then used to register this service
     */
```
Onboarding a service with the Zowe API Meditation Layer without an onboarding enabler

This article is part of a series of guides to onboard a REST service with the Zowe API Mediation Layer (API ML). Onboarding with API ML makes services accessible through the API Gateway and visible in the API Catalog. Once a service is successfully onboarded, users can see if the service is currently available and accepting requests.

This guide describes how a REST service can be onboarded with the Zowe API ML independent of the language used to write the service. As such, this guide does not describe how to onboard a service with a specific enabler. Similarly, various Eureka client implementations are not used in this onboarding method.

**Tip:** If possible, we recommend that you onboard your service using the API ML enabler libraries. The approach described in this article should only be used if other methods to onboard your service are not suitable.
For more information about how to onboard a REST service, see the following links:

- [Onboarding Overview](#) on page 211
- [python-eureka-client](#)
- [eureka-js-client](#)
- [Sample REST API Service](#) on page 214

This article outlines a process to make an API service available in the API Mediation Layer by making a direct call to the Eureka Discovery Service.

  - API Mediation Layer Service onboarding metadata
    - Catalog parameters
    - Service parameters
    - Routing parameters
    - API Info Parameters
  - Sending a heartbeat to API Mediation Layer Discovery Service
  - Validating successful onboarding with the API Mediation Layer
  - [External Resources](#)

**Introduction**

The API ML Discovery Service uses Netflix/Eureka as a REST services registry. Eureka is a REST-based service that is primarily used to locate services.

Eureka endpoints are used to register a service with the API ML Discovery Service. Endpoints are also used to send a periodic heartbeat to the Discovery Service to indicate that the onboarded service is available.

**Note:** Required parameters should be defined and sent at registration time.

**Registering with the Discovery Service**

Begin the onboarding process by registering your service with the API ML Discovery Service.

Use the `POST` HTTP call to the Eureka server together with the registration configuration in the following format:

```xml
<?xml version="1.0" ?>
<instance>
  <app>{serviceId}</app>
  <ipAddr>{ipAddress}</ipAddr>
  <port enabled="false">{port}</port>
  <securePort enabled="true">{port}</securePort>
  <hostName>{hostname}</hostName>
  <vipAddress>{serviceId}</vipAddress>
  <secureVipAddress>{serviceId}</secureVipAddress>
  <instanceId>{instanceId}</instanceId>
  <dataCenterInfo>
    <name>MyOwn</name>
  </dataCenterInfo>
  <metadata>...
  </metadata>
</instance>
```

The following code block shows the format of the parameters in your `POST` call, which are sent to the Eureka registry at the time of registration.
where:

- **app**
  uniquely identifies one or more instances of a microservice in the API ML.

  The API ML Gateway uses the `serviceId` for routing to the API service instances. As such, the `serviceId` is part of the service URL path in the API ML Gateway address space.

  **Important!** Ensure that the service ID is set properly with the following considerations:
  
  - The service ID value contains only lowercase alphanumeric characters.
  - The service ID does not contain more than 40 characters.
  - The same service ID is only set for multiple API service instances to support API scalability. When two API services use the same service ID, the API Gateway considers the services as clones of each other. An incoming API request can be routed to either of them through load balancing.

**Example:**

- If the `serviceId` is `sampleservice`, the service URL in the API ML Gateway address space appears as:
  
  ```
  https://gateway-host:gateway-port/api/v1/sampleservice/...
  ```

- **ipAddr**
  specifies the IP address of this specific service instance.

- **port**
  specifies the port of the instance when you use Http. For Http, set `enabled` to `true`.

- **securePort**
  specifies the port of the instance for when you use Https. For Https, set `enabled` to `true`.

- **hostname**
  specifies the hostname of the instance.

- **vipAddress**
  specifies the `serviceId` when you use Http.

  **Important!** Ensure that the value of `vipAddress` is the same as the value of `app`.

- **secureVipAddress**
  specifies the `serviceId` when you use Https.

  **Important!** Ensure that the value of `secureVipAddress` is the same as the value of `app`.

- **instanceId**
  specifies a unique id for the instance. Define a unique value for the `instanceId` in the following format:
  
  `{hostname}:{serviceId}:{port}`

- **metadata**
  specifies the set of parameters described in the following section addressing API ML service metadata.

**API Mediation Layer Service onboarding metadata**

At registration time, provide metadata in the following format. Metadata parameters contained in this code block are described in the following section.

```xml
<instance>
  <metadata>
    <apiml.catalog.tile.id>samples</apiml.catalog.tile.id>
    <apiml.catalog.tile.title>Sample API Mediation Layer Applications</apiml.catalog.tile.title>
  </metadata>
</instance>
```
Metadata parameters are broken down into the following categories:

- **Catalog parameters**
- **Service parameters**
- **Routing parameters**
- **Authentication parameters**
- **API Info parameters**

**Catalog parameters**

Catalog parameters are grouped under the prefix: `apiml.catalog.tile`.

The API ML Catalog displays information about services registered with the API ML Discovery Service. Information displayed in the Catalog is defined in the metadata provided by your service during registration. The Catalog groups correlated services in the same tile when these services are configured with the same `catalog.tile.id` metadata parameter.

The following parameters are used to populate the API Catalog:

- **apiml.catalog.tile.id**
  
  This parameter specifies the specific identifier for the product family of API services. This is a value used by the API ML to group multiple API services into a single tile. Each identifier represents a single API dashboard tile in the Catalog.

  **Important!** Specify a value that does not interfere with API services from other products. We recommend that you use your company and product name as part of the ID.

- **apiml.catalog.tile.title**
  
  This parameter specifies the title of the API services product family. This value is displayed in the API Catalog dashboard as the tile title.
• **apiml.catalog.tile.description**

  This parameter is the detailed description of the API services product family. This value is displayed in the API Catalog UI dashboard as the tile description.

• **apiml.catalog.tile.version**

  This parameter specifies the semantic version of this API Catalog tile.

  **Note:** Ensure that you increase the version number when you introduce changes to the API service product family details.

**Service parameters**

Service parameters are grouped under the prefix: `apiml.service`

The following parameters define service information for the API Catalog:

• **apiml.service.title**

  This parameter specifies the human-readable name of the API service instance.

  This value is displayed in the API Catalog when a specific API service instance is selected.

• **apiml.service.description**

  This parameter specifies a short description of the API service.

  This value is displayed in the API Catalog when a specific API service instance is selected.

• **apiml.enableUrlEncodedCharacters**

  When this parameter is set to `true`, the Gateway allows encoded characters to be part of URL requests redirected through the Gateway. The default setting of `false` is the recommended setting. Change this setting to `true` only if you expect certain encoded characters in your application's requests.

  **Important!** When the expected encoded character is an encoded slash or backslash (%2F, %5C), make sure the Gateway is also configured to allow encoded slashes. For more info see Installation roadmap on page 71.

**Routing parameters**

Routing parameters are grouped under the prefix: `apiml.routes`

The API routing group provides necessary routing information used by the API ML Gateway when routing incoming requests to the corresponding service. A single route can be used to make direct REST calls to multiple resources or API endpoints. The route definition provides rules used by the API ML Gateway to rewrite the URL in the Gateway address space.

Routing information consists of two parameters per route:

• **gatewayUrl**

• **serviceUrl**

  These two parameters together specify a rule of how the API service endpoints are mapped to the API Gateway endpoints.

The following snippet is an example of the API routing information properties.

**Example:**

```
<apiml.routes.api__v1.gatewayUrl>api/v1</apiml.routes.api__v1.gatewayUrl>
<apiml.routes.api__v1.serviceUrl>/sampleclient/api/v1</apiml.routes.api__v1.serviceUrl>
```

where:

• **apiml.routes.{route-prefix}.gatewayUrl**

  The `gatewayUrl` parameter specifies the portion of the gateway URL which is replaced by the `serviceUrl` path.
• **apiml.routes.(route-prefix).serviceUrl**

  The `serviceUrl` parameter provides a portion of the service instance URL path which replaces the `gatewayUrl` part.

**Note:** The routes configuration used for a direct REST call to register a service must also contain a prefix before the `gatewayUrl` and `serviceUrl`. This prefix is used to differentiate the routes. This prefix must be provided manually when XML configuration is used.

For more information about API ML routing, see [API Gateway Routing](#).

**Authentication parameters**

Authentication parameters are grouped under the prefix: `apiml.authentication`. When not specified, the default values are used.

This parameter enables a service to accept the Zowe JWT token. The API Gateway translates the token to an authentication method supported by a service.

The following parameters define the service authentication method:

• **apiml.authentication.scheme**

  This parameter specifies a service authentication scheme. The following schemes are supported by the API Gateway:

  • **bypass**

    This value specifies that the token is passed unchanged to the service.

    **Note:** This is the default scheme when no authentication parameters are specified.

  • **zoweJwt**

    This value specifies that a service accepts the Zowe JWT token. No additional processing is done by the API Gateway.

  • **httpBasicPassTicket**

    This value specifies that a service accepts PassTickets in the Authorization header of the HTTP requests using the basic authentication scheme. It is necessary to provide a service APPLID in the `apiml.authentication.applid` parameter.

    **Tip:** For more information, see [Enabling PassTicket creation for API Services that Accept PassTickets](#) on page 239.

  • **zosmf**

    This value specifies that a service accepts z/OSMF LTPA (Lightweight Third-Party Authentication). This scheme should only be used for a z/OSMF service used by the API Gateway Authentication Service, and other z/OSMF services that are using the same LTPA key.

    **Tip:** For more information about z/OSMF Single Sign-on, see [Establishing a single sign-on environment](#).

• **apiml.authentication.applid**

  This parameter specifies a service APPLID. This parameter is valid only for the `httpBasicPassTicket` authentication scheme.

**API Info parameters**

API Info parameters are grouped under the prefix: `apiml.apiInfo`.

REST services can provide multiple APIs. Add API info parameters for each API that your service wants to expose on the API ML. These parameters provide information for API (Swagger) documentation that is displayed in the API Catalog.

The following parameters provide the information properties of a single API:
• **apiml.apiInfo.{api-index}.apiId**
  The API ID uniquely identifies the API in the API ML. Multiple services can provide the same API. The API ID can be used to locate the same APIs that are provided by different services. The creator of the API defines this ID. The API ID needs to be a string of up to 64 characters that uses lowercase alphanumerical characters and a dot: .
  
  **Tip:** We recommend that you use your organization as the prefix.

• **apiml.apiInfo.{api-index}.version**
  This parameter specifies the API version. This parameter is used to correctly retrieve the API documentation according to the requested version of the API.

• **apiml.apiInfo.{api-index}.gatewayUrl**
  This parameter specifies the base path at the API Gateway where the API is available. Ensure that this value is the same path as the gatewayUrl value in the routes sections for the routes, which belong to this API.

• **apiml.apiInfo.{api-index}.swaggerUrl**
  (Optional) This parameter specifies the Http or Https address where the Swagger JSON document is available.

• **apiml.apiInfo.{api-index}.documentationUrl**
  (Optional) This parameter specifies the link to the external documentation. A link to the external documentation can be included along with the Swagger documentation.

**Note:** The {api-index} is used to differentiate the service APIs. This index must be provided manually when XML configuration is used. In the following example, 0 represents the api-index.

```xml
<apiml.apiInfo.0.apiId>org.zowe.sampleclient</apiml.apiInfo.0.apiId>
<apiml.apiInfo.0.swaggerUrl>https://hostname/sampleclient/api-doc</apiml.apiInfo.0.swaggerUrl>
<apiml.apiInfo.0.gatewayUrl>api/v1</apiml.apiInfo.0.gatewayUrl>
<apiml.apiInfo.0.documentationUrl>https://www.zowe.org/</apiml.apiInfo.0.documentationUrl>
```

**Sending a heartbeat to API Mediation Layer Discovery Service**

After registration, a service must send a heartbeat periodically to the Discovery Service to indicate that the service is available. When the Discovery Service does not receive a heartbeat, the service instance is deleted from the Discovery Service.

If the server does not receive a renewal in 90 seconds, it removes the instance from its registry.

**Note:** We recommend that the interval for the heartbeat is no more than 30 seconds.

Use the Http PUT method in the following format to tell the Discovery Service that your service is available:

```
https://{eureka_hostname}:{eureka_port}/eureka/apps/{serviceId}/instance
```

**Validating successful onboarding with the API Mediation Layer**

Ensure that you successfully onboarded a service with the API Mediation Layer.

**Follow these steps:**

1. In your Http client such as HTTPie, Postman, or cURL use the Http GET method in the following format to query the Discovery Service for your service instance information:

   ```
   http://{eureka_hostname}:{eureka_port}/eureka/apps/{serviceId}
   ```

2. Check your service metadata.

**Response example:**

```xml
<application>
  <name>{serviceId}</name>
  <instanceId>{hostname}:{serviceId}:{port}</instanceId>
</application>
```
3. Check that your API service is displayed in the API Catalog and all information including API documentation is correct.

4. Check that you can access your API service endpoints through the Gateway.

5. (Optional) Check that you can access your API service endpoints directly outside of the Gateway.

**Onboard a REST API without code changes required**

As a user of Zowe™, onboard an existing REST API service to the Zowe™ API Mediation Layer without changing the code of the API service. This form of onboarding is also referred to as, “static onboarding”.

**Note:** When developing a new service, it is not recommended to onboard a REST service using this method, as this method is non-native to the API Mediation Layer. For a complete list of methods to onboard a REST service natively to the API Mediation Layer, see the Service Onboarding Guides on page 212.
The following procedure outlines the steps to onboard an API service through the API Gateway in the API Mediation Layer without requiring code changes.

- **Identify the API that you want to expose**
- **Define your service and API in YAML format** on page 227
- **Route your API** on page 228
- **Route your API** on page 229
- **Customize configuration parameters** on page 229
- **Add and validate the definition in the API Mediation Layer running on your machine** on page 234
- **Add a definition in the API Mediation Layer in the Zowe runtime** on page 235
- **(Optional) Check the log of the API Mediation Layer** on page 236
- **(Optional) Reload the services definition after the update when the API Mediation Layer is already started** on page 236

**Tip:** For more information about the structure of APIs and which APIs to expose in the Zowe API Mediation Layer, see the **Onboarding Overview** on page 211.

### Identify the APIs that you want to expose

The first step in API service onboarding is to identify the APIs that you want to expose.

**Follow these steps:**

1. Identify the following parameters of your API service:
   - Hostname
   - Port
   - (Optional) base path where the service is available. This URL is called the base URL of the service.

   **Example:**
   In the sample service described in the **Sample REST API Service** on page 214, the URL of the service is:

2. Identify the API of the service that you want to expose through the API Gateway.

   **Example:**
   The API provided by the sample service is a second version of the Pet Store API. All the endpoints to be onboarded are available through **http://localhost:8080/v2/** URL. This REST API is therefore available at the path `/v2` relative to base URL of the service. There is no version 1 in this case.

3. Choose the **service ID** of your service. The **service ID** identifies the service uniquely in the API Gateway. The **service ID** is an alphanumeric string in lowercase ASCII.

   **Example:**
   In the sample service, the **service ID** is `petstore`.

4. Decide which URL to use to make this API available in the API Gateway. This URL is referred to as the gateway URL and is composed of the API type and the major version. The usually used types are: `api`, `ui` and `ws` but you can use any valid URL element you want.

   **Example:**
   In the sample service, we provide a REST API. The first segment is `/api` as the service provides only one REST API. To indicate that this is version 2, the second segment is `/v2`. This version is required by the Gateway. If your service does not have a version, use `v1` on the Gateway.

### Define your service and API in YAML format

After you identify the APIs you want to expose, you need to define your service and API in YAML format as presented in the following sample **petstore** service example.

**Example:**
To define your service in YAML format, provide the following definition in a YAML file as in the following sample petstore service. This configuration is the minimal configuration necessary for the Gateway to properly route the requests to the application and to show the Service in the Catalog UI.

**Note:** For more details about configuration, see Customize configuration parameters on page 229.

```yaml
services:
  - serviceId: petstore
catalogUiTileId: static
instanceBaseUrls:
  - http://localhost:8080
routes:
  - gatewayUrl: api/v2
    serviceRelativeUrl: /v2
authentication:
  scheme: httpBasicPassTicket
  applid: ZOWEAPPL
apiInfo:
  - apiId: io.swagger.petstore
gatewayUrl: api/v2
catalogUiTiles:
  static:
    title: Static API services
    description: Services which demonstrate how to make an API service discoverable in the APIML ecosystem using YAML definitions
```

In this example, a suitable name for the file is petstore.yml.

**Notes:**

- The filename does not need to follow specific naming conventions but it requires the .yml extension.
- The file can contain one or more services defined under the services: node.
- Each service has a service ID. In this example, the service ID is petstore. The service id is used as a part of the request URL towards the Gateway. It is removed by the Gateway when forwarding the request to the service.
- The service can have one or more instances. In this case, only one instance http://localhost:8080 is used.
- One API is provided and the requests with the relative base path api/v2 at the API Gateway (full gateway URL: https://gateway:port/api/v2/serviceId/...) are routed to the relative base path /v2 at the full URL of the service (http://localhost:8080/v2/...).
- The file on USS should be encoded in ASCII to be read correctly by the API Mediation Layer.

**Tips:**

- There are more examples of API definitions at this link.
- For more details about how to use YAML format, see this link.

**Route your API**

Routing is the process of sending requests from the API Gateway to a specific API service. Route your API by using the same format as in the following petstore example. The configuration parameters are explained in Customize configuration parameters on page 229. Gateway URL format:

```
https://{gatewayHost}:{port}/api/v{majorVersion}/{serviceId}/{resource}
```

**Note:** The API Gateway differentiates major versions of an API.

**Example:**

When the configuration parameters are:

```yaml
services:
```
To access API version 2 of the service petstore, gateway URL will be:

https://gateway-host:port/api/v2/petstore

It will be routed to:

https://localhost:8080/v2

To access resource pets of the petstore version 2 API, gateway URL will be:

https://gateway:port/api/v2/petstore/pets

It will be routed to:

https://localhost:8080/v2/pets

Note: This method enables you to access the service through a stable URL, and move the service to another machine without changing the gateway URL. Accessing a service through the API Gateway also enables you to have multiple instances of the service running on different machines to achieve high-availability.

Customize configuration parameters

This part contains a more complex example of the configuration and an explanation of all the possible parameters:

```
  services:
    - serviceId: petstore
catalogUiTileId: static
title: Petstore Sample Service
description: This is a sample server Petstore service
instanceBaseUrls:
  - http://localhost:8080
  homePageRelativeUrl: /home # Normally used for informational purposes
  for other services to use it as a landing page
  statusPageRelativeUrl: /application/info  # Appended to the
  instanceBaseUrl
  healthCheckRelativeUrl: /application/health  # Appended to the
  instanceBaseUrl
routes:
  - gatewayUrl: api/v2
    serviceRelativeUrl: /v2
  authentication:
    scheme: httpBasicPassTicket
    applid: ZOWEAPPL
apiInfo:
  - apiId: io.swagger.petstore
gatewayUrl: api/v2
  swaggerUrl: http://localhost:8080/v2/swagger.json
documentationUrl: https://petstore.swagger.io/
  version: 2.0.0
  customMetadata:
    yourqualifier:
      key1: value1
      key2: value2
catalogUiTiles:
```
static:
  title: Static API services
  description: Services which demonstrate how to make an API service discoverable in the APIML ecosystem using YAML definitions

additionalServiceMetadata:
  - serviceId: petstore
    mode: UPDATE # How to update UPDATE=only missing, FORCE_UPDATE=update all set values
    authentication:
      scheme: bypass

• serviceId

This parameter specifies the service instance identifier that is registered in the API Mediation Layer installation. The service ID is used in the URL for routing to the API service through the Gateway. The service ID uniquely identifies the service in the API Mediation Layer. The system administrator at the customer site defines this parameter.

Important! Ensure that the service ID is set properly with the following considerations:

• When two API services use the same service ID, the API Gateway considers the services to be clones (i.e. two instances for the same service). An incoming API request can be routed to either of them.
• The same service ID should be set only for multiple API service instances for API scalability.
• The service ID value must contain only lowercase alphanumeric characters.
• The service ID cannot contain more than 40 characters.
• The service ID is linked to security resources. Changes to the service ID require an update of security resources.

Examples:

• If the customer system administrator sets the service ID to monitoringpr1, the API URL in the API Gateway appears as the following URL:
  https://gateway:port/api/v1/monitoringpr1/...
• If customer system administrator sets the service ID to authenticationprod1, the API URL in the API Gateway appears as the following URL:
  http://gateway:port/api/v1/authenticationprod1/...

• title

This parameter specifies the human readable name of the API service instance (for example, Monitoring Prod or systemInfo LPAR1). This value is displayed in the API catalog when a specific API service instance is selected. This parameter is externalized and set by the customer system administrator.

Tip: We recommend that you provide a specific default value of the title. Use a title that describes the service instance so that the end user knows the specific purpose of the service instance.

• description

This parameter specifies a short description of the API service.

Examples:

• Monitoring Service - Production Instance
• System Info Service running on LPAR1

This value is displayed in the API Catalog when a specific API service instance is selected. This parameter is externalized and set by the customer system administrator.

Tip: Describe the service so that the end user knows the function of the service.
• **instanceBaseUrls**
  This parameter specifies a list of base URLs to your service's REST resource. It will be the prefix for the following URLs:
  
  • **homePageRelativeUrl**
  • **statusPageRelativeUrl**
  • **healthCheckRelativeUrl**

  **Examples:**
  
  • `- http://host:port/ftpservice for an HTTP service`
  • `- https://host:port/source-code-mngmnt for an HTTPS service`

  You can provide one URL if your service has one instance. If your service provides multiple instances for the high-availability then you can provide URLs to these instances.

  **Examples:**
  
  • `- https://host1:port1/source-code-mngmnt`
  • `- https://host2:port2/source-code-mngmnt`

• **homePageRelativeUrl**
  This parameter specifies the relative path to the homepage of your service. The path should start with `/`. If your service has no homepage, omit this parameter. The path is relative to the instanceBaseUrls.

  **Examples:**
  
  • `homePageRelativeUrl: `/ The service has homepage with URL `${baseUrl}/`
  • `homePageRelativeUrl: `/ui/ The service has homepage with URL `${baseUrl}/${ui/`
  • `homePageRelativeUrl: The service has homepage with URL `${baseUrl}`

• **statusPageRelativeUrl**
  This parameter specifies the relative path to the status page of your service. Start this path with `/`. If you service doesn't have a status page, omit this parameter. The path is relative to the instanceBaseUrls.

  **Example:**
  
  `statusPageRelativeUrl: /application/info`
  the result URL will be:
  `
  `${baseUrl}/application/info`

• **healthCheckRelativeUrl**
  This parameter specifies the relative path to the health check endpoint of your service. Start this URL with `/`. If your service does not have a health check endpoint, omit this parameter. The path is relative to the instanceBaseUrls.

  **Example:**
  
  `healthCheckRelativeUrl: /application/health`
  This results in the URL:
  `
  `${baseUrl}/application/health`
• **routes**

  The following parameters specify the routing rules between the Gateway service and your service. Both specify how the API endpoints are mapped to the API Gateway endpoints.

  • **routes.gatewayUrl**

    The `gatewayUrl` parameter sets the target endpoint on the Gateway. This is the portion of the final URL that is Gateway specific.

    **Example:**

    For the petstore example, the full Gateway URL would be:
    
    `https://gatewayUrl:1345/api/v2/petstore/pets/1`
    
    In this case, the URL that will be called on the service is:
    
    `http://localhost:8080/v2/pets/1`

  • **routes.serviceRelativeUrl**

    The `serviceRelativeUrl` parameter points to the target endpoint on the service. This is the base path on the service called through the Gateway.

• **authentication**

  Parameters under this grouping allow a service to accept the Zowe JWT token. The API Gateway translates the token to an authentication method supported by a service.

  • **authentication.scheme**

    This parameter specifies a service authentication scheme. The following schemes are supported by the API Gateway:

    • **bypass**

      This value specifies that the token is passed unchanged to the service. This is the default scheme when no authentication parameters are specified.

    • **zoweJwt**

      This value specifies that a service accepts the Zowe JWT token. No additional processing is done by the API Gateway.

    • **httpBasicPassTicket**

      This value specifies that a service accepts PassTickets in the Authorization header of the HTTP requests using the basic authentication scheme. It is necessary to provide a service APPLID in the `apiml.authentication.applid` parameter.

      **Tip:** For more information, see Enabling PassTicket creation for API Services that Accept PassTickets on page 239.

    • **zosmf**

      This value specifies that a service accepts z/OSMF LTPA (Lightweight Third-Party Authentication). This scheme should only be used for a z/OSMF service used by the API Gateway Authentication Service, and other z/OSMF services that are using the same LTPA key.

      **Tip:** For more information about z/OSMF Single Sign-on, see Establishing a single sign-on environment.

  • **authentication.applid**

    This parameter specifies a service APPLID. This parameter is only valid for the `httpBasicPassTicket` authentication scheme.
• **apiInfo**

This section defines APIs that are provided by the service. Currently, only one API is supported.

• **apiInfo.apiUrl**

This parameter specifies the API identifier that is registered in the API Mediation Layer installation. The API ID uniquely identifies the API in the API Mediation Layer. The same API can be provided by multiple services. The API ID can be used to locate the same APIs that are provided by different services.

The creator of the API defines this ID. The API ID needs to be a string of up to 64 characters that uses lowercase alphanumeric characters and a dot: ..

**Tip:** We recommend that you use your organization as the prefix.

**Examples:**

• org.zowe.file
• com.ca.sysview
• com.ibm.zosmf

• **apiInfo.gatewayUrl**

This parameter specifies the base path at the API Gateway where the API is available. Ensure that this path is the same as the `gatewayUrl` value in the `routes` sections.

• **apiInfo.swaggerUrl**

(Optional) This parameter specifies the HTTP or HTTPS address where the Swagger JSON document is available.

• **apiInfo.documentationUrl**

(Optional) This parameter specifies a URL to a website where external documentation is provided. This can be used when `swaggerUrl` is not provided.

• **apiInfo.version**

(Optional) This parameter specifies the actual version of the API in semantic versioning format. This can be used when `swaggerUrl` is not provided.

• **customMetadata**

(Optional) Additional metadata can be added to the instance information that is registered in the Discovery Service in the `customMetadata` section. This information is propagated from the Discovery Service to the onboarded services (clients). In general, additional metadata do not change the behavior of the client. Some specific metadata can configure the functionality of the API Mediation Layer. Such metadata are generally prefixed with the `apiml` qualifier. We recommend you define your own qualifier, and group all metadata you wish to publish under this qualifier.

• **customMetadata.apiml.enableUrlEncodedCharacters**

When this parameter is set to `true`, the Gateway allows encoded characters to be part of URL requests redirected through the Gateway. The default setting of `false` is the recommended setting. Change this setting to `true` only if you expect certain encoded characters in your application's requests.

**Important!** When the expected encoded character is an encoded slash or backslash (`%2F`, `%5C`), make sure the Gateway is also configured to allow encoded slashes. For more info see [Installation roadmap](#) on page 71.

• **catalogUiTileId**

This parameter specifies the unique identifier for the API services group. This is the grouping value used by the API Mediation Layer to group multiple API services together into "tiles". Each unique identifier represents a single API Catalog UI dashboard tile. Specify the value based on the ID of the defined tile.

• **catalogUiTile**

This section contains definitions of tiles. Each tile is defined in a section that has its tile ID as a key. A tile can be used by multiple services.
tile1:
  title: Tile 1
  description: This is the first tile with ID tile1

tile2:
  title: Tile 2
  description: This is the second tile with ID tile2

- **catalogUiTile.{tileId}.title**
  
  This parameter specifies the title of the API services product family. This value is displayed in the API Catalog UI dashboard as the tile title.

- **catalogUiTile.{tileId}.description**
  
  This parameter specifies the detailed description of the API Catalog UI dashboard tile. This value is displayed in the API Catalog UI dashboard as the tile description.

- **additionalServiceMetadata**
  
  This section contains a list of changes that allows adding or modifying metadata parameters for the corresponding service.

  - **additionalServiceMetadata.serviceId**
    
    This parameter specifies the service identifier for which metadata is updated.

  - **additionalServiceMetadata.mode**
    
    This parameter specifies how the metadata are updated. The following modes are available:

    - **UPDATE**
      
      Only missing parameters are added. Already existing parameters are ignored.

    - **FORCE_UPDATE**
      
      All changes are applied. Existing parameters are overwritten.

  - **additionalServiceMetadata.{updatedParameter}**
    
    This parameter specifies any metadata parameters that are updated.

**Add and validate the definition in the API Mediation Layer running on your machine**

After you define the service in YAML format, you are ready to add your service definition to the API Mediation Layer ecosystem.

The following procedure describes how to add your service to the API Mediation Layer on your local machine.

**Follow these steps:**

1. Copy or move your YAML file to the `config/local/api-defs` directory in the directory with API Mediation Layer.
2. Start the API Mediation Layer services.
   
   **Tip:** For more information about how to run the API Mediation Layer locally, see [Running the API Mediation Layer on Local Machine](#).
3. Run your Java application.
   
   **Tip:** Wait for the services to be ready. This process may take a few minutes.
4. Go to the following URL to reach the API Gateway (port 10010) and see the paths that are routed by the API Gateway. If the authentication is required and the default configuration provider on local instance is used the username is user and password user:

https://localhost:10010/application/routes

The following line should appear:

/api/v2/petstore/**: "petstore"

This line indicates that requests to relative gateway paths that start with /api/v2/petstore/ are routed to the service with the service ID petstore.

You successfully defined your Java application if your service is running and you can access the service endpoints. The following example is the service endpoint for the sample application:

https://localhost:10010/api/v2/petstore/pets/1

Add a definition in the API Mediation Layer in the Zowe runtime

After you define and validate the service in YAML format, you are ready to add your service definition to the API Mediation Layer running as part of the Zowe runtime installation on z/OS.

Follow these steps:

1. Locate the Zowe instance directory. The Zowe instance directory is the directory from which Zowe was launched, or else was passed as an argument to the SDSF command used to start Zowe. If you are unsure which instance directory a particular Zowe job is using, open the JESJCL spool file and navigate to the line that contains STARTING EXEC ZWESVSTC,INSTANCE=. This is the fully qualified path to the instance directory.

   Tip: For more information, see Extensions on page 107.

   Note: We use the ${zoweInstanceDir} symbol in following instructions.

2. Add the fully qualified zFS path of your YAML file to instance.env.

   • To hold your YAML file outside of the instance directory, append the fully qualified zFS path of the YAML file to the ZWEAD_EXTERNAL_STATIC_DEF_DIRECTORIES variable in the instance.env file. This variable contains a semicolon separated list of static API extension YAML files.

   • To place your YAML file within the instance directory, copy your YAML file to the ${zoweInstanceDir}/workspace/api-mediation/api-defs directory.

   Notes:

   • The ${zoweInstanceDir}/workspace/api-mediation/api-defs directory is created the first time that Zowe starts. If you have not yet started Zowe, this directory might be missing.

   • The user ID ZWESVUSR that runs the Zowe started task must have permission to read the YAML file.

3. Ensure that your application that provides the endpoints described in the YAML file is running.

4. Restart Zowe runtime or follow steps in section (Optional) Reload the services definition after the update when the API Mediation Layer is already started on page 236 which allows you to add your static API service to an already running Zowe.

5. Go to the following URL to reach the API Gateway (default port 7554) and see the paths that are routed by the API Gateway:

https://${zoweHostname}:${gatewayHttpsPort}/application/routes

The following line should appear:

/api/v2/petstore/**: "petstore"

This line indicates that requests to the relative gateway paths that start with /api/v2/petstore/ are routed to the service with service ID petstore.
You successfully defined your Java application if your service is running and you can access its endpoints. The endpoint displayed for the sample application is:

```
https://l${zoweHostname}:${gatewayHttpsPort}/api/v2/petstore/pets/1
```

(Optional) Check the log of the API Mediation Layer

The API Mediation Layer log can contain messages based on the API ML configuration. The API ML prints the following messages to its log when the API definitions are processed:

```
Scanning directory with static services definition: config/local/api-defs
Static API definition file: /Users/plape03/workspace/api-layer/config/local/api-defs/petstore.yml
Adding static instance STATIC-localhost:petstore:8080 for service ID petstore mapped to URL http://localhost:8080
```

Note: If these messages are not displayed in the log, ensure that the API ML debug mode is active.

(Optional) Reload the services definition after the update when the API Mediation Layer is already started

The following procedure enables you to refresh the API definitions after you change the definitions when the API Mediation Layer is already running.

Follow these steps:

1. Use a REST API client to issue a POST request to the Discovery Service (port 10011):

   `http://localhost:10011/discovery/api/v1/staticApi`

   The Discovery Service requires authentication by a client certificate. If the API Mediation Layer is running on your local machine, the certificate is stored at `keystore/localhost/localhost.pem`.

   This example uses the HTTPie command-line HTTP client and is run with Python 3 installed:

   ```bash
   ```

2. Check if your updated definition is effective.

   Note: It can take up to 30 seconds for the API Gateway to pick up the new routing.

API Mediation Layer Message Service Component

The API ML Message Service component unifies and stores REST API error messages and log messages in a single file. The Message Service component enables users to mitigate the problem of message definition redundancy which helps to optimize the development process.

- Message Definition on page 236
- Creating a message on page 237
- Mapping a message on page 237
- API ML Logger on page 238

Message Definition

API ML uses a customizable infrastructure to format both REST API error messages and log messages. `yaml` files make it possible to centralize both API error messages and log messages. Messages have the following definitions:
• Message key - a unique ID in the form of a dot-delimited string that describes the reason for the message. The key enables the UI or the console to show a meaningful and localized message.

Tips:
• We recommend using the format org.zowe.sample.apiservice.{TYPE}.greeting.empty to define the message key. {TYPE} can be the api or log keyword.
• Use the message key and not the message number. The message number makes the code less readable, and increases the possibility of errors when renumbering values inside the number.
• Message number - a typical mainframe message ID (excluding the severity code)
• Message type - There are two Massage types:
  • REST API error messages: ERROR
  • Log messages: ERROR, WARNING, INFO, DEBUG, or TRACE
• Message text - a description of the issue

The following example shows the message definition.

Example:

```
messages:
  - key: org.zowe.sample.apiservice.{TYPE}.greeting.empty
    number: ZWEAS001
    type: ERROR
    text: "The provided '%s' name is empty."
```

Creating a message

Use the following classes when you create a message:

• org.zowe.apiml.message.core.MessageService - lets you create a message from a file.

Use the following process to create a message.

Follow these steps:
1. Load messages from the yaml file.

   Example:
   ```java
   MessageService messageService = new YamlMessageService();
   messageService.loadMessages("/api-messages.yml");
   messageService.loadMessages("/log-messages.yml");
   ```

2. Use the Message createMessage(String key, Object... parameters); method to create a message.

   Example:
   ```java
   Message message =
   messageService.createMessage("org.zowe.sample.apiservice.
   {TYPE}.greeting.empty", "test");
   ```

Mapping a message

You can map the Message either to a REST API response or to a log message.

When you map a REST API response, use the following methods:
• mapToView - returns a UI model as a list of API Message, and can be used for Rest API error messages
- `mapToApiMessage` - returns a UI model as a single API Message

The following example is a result of using the `mapToView` method.

**Example:**

```json
{
  "messages": [
    {
      "messageKey": "org.zowe.sample.apiservice.{TYPE}.greeting.empty",
      "messageType": "ERROR",
      "messageNumber": "ZWEASA001",
      "messageContent": "The provided 'test' name is empty."
    }
  ]
}
```

The following example is the result of using the `mapToApiMessage` method.

**Example:**

```json
{
  "messageKey": "org.zowe.sample.apiservice.{TYPE}.greeting.empty",
  "messageType": "ERROR",
  "messageNumber": "ZWEASA001",
  "messageContent": "The provided 'test' name is empty."
}
```

**API ML Logger**

The `org.zowe.apiml.message.log.ApimLogger` component controls messages through the Message Service component.

The following example uses the `log` message definition in a `yaml` file.

**Example:**

```yaml
messages:
  - key: org.zowe.sample.apiservice.log.greeting.empty
    number: ZWEASA001
    type: DEBUG
    text: "The provided '%s' name is empty."
```

When you map a log message, use `mapToLogMessage` to return a log message as text. The following example is the output of the `mapToLogMessage`.

**Example:**

```
ZWEASA001D The provided 'test' name is empty. {43abb594-3415-4ed5-a0b5-23e306a91124}
```

Use the `ApimlLogger` to log messages which are defined in the `yaml` file.

**Example:**

```java
package org.zowe.apiml.client.configuration;

import org.zowe.apiml.message.core.MessageService;
import org.zowe.apiml.message.core.MessageType;
import org.zowe.apiml.message.log.ApimlLogger;

public class SampleClass {
    private final ApimlLogger logger;
```
public SampleClass(MessageService messageService) {
    logger = ApimlLogger.of(SampleClass.class, messageService);
}

public void process() {
    logger.log("org.zowe.sample.apiservice.log.greeting.empty", "test");
}

The following example shows the output of a successful ApimlLogger usage.

Example:

DEBUG (c.c.m.c.c.SampleClass) ZWEASA001D The provided 'test' name is empty.
{43abb594-3415-4ed5-a0b5-23e306a91124}

Enabling PassTicket creation for API Services that Accept PassTickets

As system programmer, you can configure Zowe to use PassTickets for API services that are compatible to accept them to authenticate your service with the API Mediation Layer.

Overview

API clients can use a Zowe JWT token to access an API service even if the API service itself does not support the JWT token. The Zowe JWT token is available through the API Gateway authentication endpoint.

When an API client provides a valid Zowe JWT token to the API ML, the API Gateway then generates a valid PassTicket for any API service that supports PassTickets. The API Gateway then uses the PassTicket to access that API service. The API Gateway provides the user ID and password in the Authorization header of the HTTP requests using the Basic authentication scheme.

- Outline for enabling PassTicket support on page 239
- Security configuration that allows the Zowe API Gateway to generate PassTickets for an API service on page 240
  - CA ACF2 on page 240
  - CA Top Secret on page 240
  - RACF on page 240
- API services that support PassTickets on page 240
  - API Services that register dynamically with API ML that provide authentication information on page 240
  - API Services that register dynamically with API ML but do not provide metadata on page 241
  - API services that are defined using a static YAML definition on page 241
- Adding YAML configuration to API services that register dynamically with API ML on page 241

Outline for enabling PassTicket support

The following steps outline the procedure for enabling PassTicket Support:

1. Follow the API service documentation that explains how to activate support for PassTickets.
   - The PassTickets for the API service must have the replay protection switched off. The PassTickets are exchanged between Zowe API Gateway and the API Service in a secure mainframe environment.
2. Record the value of the APPLID of the API service.
3. Enable the Zowe started task user ID to generate PassTickets for the API service.
4. Enable PassTicket support in the API Gateway for your API service.

Note: PassTickets must be enabled for every user who requires access to the API service.
Security configuration that allows the Zowe API Gateway to generate PassTickets for an API service

Consult with your security administrator to issue security commands to allow the Zowe started task user ID to generate PassTickets for the API service.

Use the following variables to generate PassTickets for the API service to enable the Zowe started task user ID:

- `<applid>` is the APPLID value used by the API service for PassTicket support (e.g. `OMVSAPPL`)
- `<zowesrv>` is Zowe started task user ID used during the Zowe installation

Replace the variables in the following examples with actual values.

**CA ACF2**

Grant the Zowe started task user ID permission to generate PassTickets for users of that API service. The following code is an example of security commands that need to be issued.

Example:

```plaintext
ACF
SET RESOURCE(PTK)
RECKEY IRRPTAUTH ADD(<applid>.- UID(<zowesrv>) SERVICE(UPDATE,READ) ALLOW)
F ACF2,REBUILD(PTK),CLASS(P)
END
```

**CA Top Secret**

Grant the Zowe started task user ID permission to generate PassTickets for users of that API service.

Example:

```plaintext
TSS PERMIT(<zowesrv>) PTKTDATA(IRRPTAUTH.<applid>.) ACCESS(READ,UPDATE)
TSS REFRESH
```

**RACF**

To enable PassTicket creation for API service users, define the profile `IRRPTAUTH.<applid>*` in the `PTKTDATA` class and set the universal access authority to `NONE`.

Grant the Zowe started task user ID permission to generate PassTickets for users of that API service.

Example:

```plaintext
RDEFINE PTKTDATA IRRPTAUTH.<applid>* UACC(NONE)
PERMIT IRRPTAUTH.<applid>* CL(PTKTDATA) ID(<zowesrv>) ACCESS(UPDATE)
SETROPTS RACLIST(PTKTDATA) REFRESH
```

**API services that support PassTickets**

The following types of API services support PassTickets:

- **API Services that register dynamically with API ML that provide authentication information** on page 240
- **API Services that register dynamically with API ML but do not provide metadata** on page 241
- **API services that are defined using a static YAML definition** on page 241

**API Services that register dynamically with API ML that provide authentication information**

API services that support Zowe API Mediation Layer and use dynamic registration to the Discovery Service already provide metadata that enables PassTicket support.

As a system programmer, you are not required to do anything in this case. All required information is provided by the API service automatically.
API Services that register dynamically with API ML but do not provide metadata

Some services can use PassTickets but the API ML does not recognize that the service can accept PassTickets. For such services, you can provide additional service metadata externally in the same file that contains the static YAML definition. The static YAML definitions are described in Onboard a REST API without code changes required on page 226.

Add the following section to the YAML file with a static definition:

```yaml
additionalServiceMetadata:
  - serviceId: <serviceId>
    mode: UPDATE
    authentication:
      scheme: httpBasicPassTicket
      applid: <applid>
```

where:

- `<serviceId>` is the service ID of the service to which you want to add metadata.

API services that are defined using a static YAML definition

Add the following metadata to the same level as the `serviceId`:

Example:

```yaml
- serviceId: ...
  authentication:
    scheme: httpBasicPassTicket
    applid: TSTAPPL
```

Note: The fields in this example are explained later in this article.

Adding YAML configuration to API services that register dynamically with API ML

As a developer of an API service that registers dynamically with the API ML, you need to provide additional metadata to tell the API Gateway to use PassTickets. Additional metadata tells the API Gateway how to generate them. The following code shows an example of the YAML configuration that contains this metadata.

Example:

```yaml
authentication:
  scheme: httpBasicPassTicket
  applid: <applid>
```

where:

- `httpBasicPassTicket` is the value that indicates that the HTTP Basic authentication scheme is used with PassTickets.
- `<applid>` is the APPLID value that is used by the API service for PassTicket support (e.g. OMVSAPPL).
Developing for Zowe Application Framework

Overview

You can create application plug-ins to extend the capabilities of the Zowe™ Application Framework. An application plug-in is an installable set of files that present resources in a web-based user interface, as a set of RESTful services, or in a web-based user interface and as a set of RESTful services.

Read the following topics to get started with extending the Zowe Application Framework.

How Zowe Application Framework works

Read the following topics to learn how Zowe Application Framework works:

- Building plugin apps on page 246
- Plug-ins definition and structure on page 243
- Dataservices on page 251
- Zowe Desktop and window management on page 263
- Configuration Dataservice on page 266
- URI Broker on page 271
- Application-to-application communication on page 273
- Error reporting UI on page 278
- Logging utility on page 280

Tutorials

The following tutorials are available in Github.

Samples

Zowe allows extensions to be written in any UI framework through the use of an Iframe, or Angular and React natively. In this section, code samples of various use-cases will be provided with install instructions.

::: warning Troubleshooting Suggestions: If you are running into issues, try these suggestions:

- Restart the Zowe Server/ VM.
- Double check that the name in the plugins folder matches your identifier in pluginsDefinition.json located in the Zowe root.
- After logging into the Zowe desktop, use the Chrome or Firefox developer tools and navigate to the "network" tab to see what errors you are getting.
• Check each file with `cat <filename>` to be sure it wasn’t corrupted while uploading. If files were corrupted, try uploading using a different method like SCP or SFTP.

---

This sample is included as the first part of a tutorial detailing communication between separate Zowe apps. It should be installed on your system before starting the User Browser Workshop App Tutorial. The App’s scenario is that it has been opened to submit a task report to a set of users who can handle the task. In this case, it is a bug report. We want to find engineers who can fix this bug, but this App does not contain a directory listing for engineers in the company, so we need to communicate with some App that does provide this information. In this tutorial, you must build an App which is called by this App in order to list engineers, is able to be filtered by the office that they work from, and is able to submit a list of engineers which would be able to handle the task.

After installing this app on your system, follow directions in the User Browser Workshop App Tutorial to enable app-to-app communication.

---

**Plug-ins definition and structure**

The Zowe™ Application Server (zlux-server-framework) enables extensibility with application plug-ins. Application plug-ins are a subcategory of the unit of extensibility in the server called a plug-in.

The files that define a plug-in are located in the `pluginsDir` directory.

**Application plug-in filesystem structure**

An application plug-in can be loaded from a filesystem that is accessible to the Zowe Application Server, or it can be loaded dynamically at runtime. When accessed from a filesystem, there are important considerations for the developer and the user as to where to place the files for proper build, packaging, and operation.

**Root files and directories**

The root of an application plug-in directory contains the following files and directories.

`pluginDefinition.json`

This file describes an application plug-in to the Zowe Application Server. (A plug-in is the unit of extensibility for the Zowe Application Server. An application plug-in is a plug-in of the type "Application", the most common and visible type of plug-in.) A definition file informs the server whether the application plug-in has server-side dataservices, client-side web content, or both. The attributes of this file and how it is found by the server are described in the Plugin Definition article.

**Dev and source content**

Aside from demonstration or open source application plug-ins, the following directories should not be visible on a deployed server because the directories are used to build content and are not read by the server.

`nodeServer`

When an application plug-in has router-type dataservices, they are interpreted by the Zowe Application Server by attaching them as ExpressJS routers. It is recommended that you write application plug-ins using Typescript, because it facilitates well-structured code. Use of Typescript results in build steps because the pre-transpilation Typescript...
content is not to be consumed by NodeJS. Therefore, keep server-side source code in the nodeServer directory. At runtime, the server loads router dataservices from the lib on page 244 directory.

**webClient**

When an application plug-in has the `webContent` attribute in its definition, the server serves static content for a client. To optimize loading of the application plug-in to the user, use Typescript to write the application plug-in and then package it using Webpack. Use of Typescript and Webpack result in build steps because the pre-transpilation Typescript and the pre-webpack content are not to be consumed by the browser. Therefore, separate the source code from the served content by placing source code in the `webClient` directory.

**Runtime content**

At runtime, the following set of directories are used by the server and client.

**lib**

The `lib` directory is where router-type dataservices are loaded by use in the Zowe Application Server. If the JS files that are loaded from the `lib` directory require NodeJS modules, which are not provided by the server base (the modules `zlux-server-framework` requires are added to `NODE_PATH` at runtime), then you must include these modules in `lib/node_modules` for local directory lookup or ensure that they are found on the `NODE_PATH` environment variable. `nodeServer/node_modules` is not automatically accessed at runtime because it is a dev and build directory.

**web**

The `web` directory is where the server serves static content for an application plug-in that includes the `webContent` attribute in its definition. Typically, this directory contains the output of a webpack build. Anything you place in this directory can be accessed by a client, so only include content that is intended to be consumed by clients.

**Packaging applications as compressed files**

Application plug-in files can be served to browsers as compressed files in brotli (.br) or gzip (.gz) format. The file must be below the application's `/web` directory, and the browser must support the compression method. If there are multiple compressed files in the `/web` directory, the Zowe Application Server and browser perform runtime negotiation to decide which file to use.

**Location of plug-in files**

The files that define a plug-in are located in the `plugins` directory.

**pluginsDir directory**

At startup, the server reads from the `plugins` directory. The server loads the valid plug-ins that are found by the information that is provided in the JSON files.

Within the `pluginsDir` directory are a collection of JSON files. Each file has two attributes, which serve to locate a plug-in on disk:

- **location**: This is a directory path that is relative to the server's executable (such as `zlux-app-server/bin/nodeServer.sh`) at which a `pluginDefinition.json` file is expected to be found.
- **identifier**: The unique string (commonly styled as a Java resource) of a plug-in, which must match what is in the `pluginDefinition.json` file.

**Plug-in definition file**

`pluginDefinition.json` is a file that describes a plug-in. Each plug-in requires this file, because it defines how the server will register and use the backend of an application plug-in (called a `plug-in` in the terminology of the proxy server). The attributes in each file are dependent upon the `pluginType` attribute. Consider the following `pluginDefinition.json` file from sample-app:

```json
{
    "identifier": "com.rs.mvd.myplugin",
    "apiVersion": "1.0"
}
```
Plug-in attributes

There are two categories of attributes: General and Application.

General attributes

identifier

Every application plug-in must have a unique string ID that associates it with a URL space on the server.

apiVersion

The version number for the pluginDefinition scheme and application plug-in or dataservice requirements. The default is 1.0.0.

pluginVersion

The version number of the individual plug-in.

pluginType

A string that specifies the type of plug-in. The type of plug-in determines the other attributes that are valid in the definition.

• application: Defines the plug-in as an application plug-in. Application plug-ins are composed of a collection of web content for presentation in the Zowe web component (such as the Zowe Desktop), or a collection of dataservices (REST and websocket), or both.

• library: Defines the plug-in as a library that serves static content at a known URL space.

• node authentication: Authentication and Authorization handlers for the Zowe Application Server.

Application attributes

When a plug-in is of pluginType application, the following attributes are valid:

webContent

An object that defines several attributes about the content that is shown in a web UI.
dataServices
An array of objects that describe REST or websocket dataservices.

configurationData
An object that describes the resource structure that the application plug-in uses for storing user, group, and server data.

Application web content attributes
An application that has the `webContent` attribute defined provides content that is displayed in a Zowe web UI.

The following attributes determine some of this behavior:

framework
States the type of web framework that is used, which determines the other attributes that are valid in `webContent`.

- **angular2**: Defines the application as having an Angular (2+) web framework component. This is the standard for a "native" framework Zowe application.
- **iframe**: Defines the application as being external to the native Zowe web application environment, but instead embedded in an iframe wrapper.

launchDefinition
An object that details several attributes for presenting the application in a web UI.

- **pluginShortNameDefault**: A string that gives a name to the application when i18n is not present. When i18n is present, i18n is applied by using the `pluginShortNameKey`.
- **descriptionDefault**: A longer string that specifies a description of the application within a UI. The description is seen when i18n is not present. When i18n is present, i18n is applied by using the `descriptionKey`.
- **imageSrc**: The relative path (from `/web`) to a small image file that represents the application icon.

defaultWindowStyle
An object that details the placement of a default window for the application in a web UI.

- **width**: The default width of the application plug-in window, in pixels.
- **height**: The default height of the application plug-in window, in pixels.

IFrame application web content
In addition to the general web content attributes, when the framework of an application is "iframe", you must specify the page that is being embedded in the iframe. To do so, incude the attribute `startingPage` within `webContent`. `startingPage` is relative to the application's `/web` directory.

Specify `startingPage` as a relative path rather than an absolute path because the `pluginDefinition.json` file is intended to be read-only, and therefore would not work well when the hostname of a page changes.

Within an IFrame, the application plug-in still has access to the globals that are used by Zowe for application-to-application communication; simply access `window.parent.ZoweZLUX`.

Building plugin apps
You can build a plugin app by using the following steps as a model. Alternatively, you can follow the Sample Angular App tutorial.

The basic requirement for a plugin app is that static web content must be in a `/web` directory, and server and other backend files must be in a `/lib` directory. You can place other plugin source code anywhere.

Before you can build a plugin app you must install all prerequisites.
Building web content

1. On the computer where the virtual desktop is installed, use the following command to specify a value for the MVD_DESKTOP_DIR environment variable:

```
export MVD_DESKTOP_DIR=/<path>/zowe/zlux-app-manager/virtual-desktop
```

Where `<path>` is the install location of the virtual desktop.

2. Navigate to `/<plugin_dir>/webClient`. If there is no `/webClient` directory, proceed to the Building server content section below.

3. Run the `npm install` command to install any application dependencies. Check for successful return code.

4. Run one of the following commands to build the application code:
   - Run the `npm run build` command to generate static content in the `/web` directory. (You can ignore warnings as long as the build is successful.)
   - Run the `npm run start` command to compile in real-time. Until you stop the script, it compiles code changes as you make them.

Building server content

1. Navigate to the plugin directory. If there is no `/nodeServer` directory in the plugin directory, proceed to the Building Javascript content (*.js files) section below.

2. Run the `npm install` command to install any application dependencies. Check for successful return code.

3. Run one of the following commands to build the application code:
   - Run the `npm run build` command to generate static content in the `/lib` directory.
   - Run the `npm run start` command to compile in real-time. Until you stop the script, it compiles code changes as you make them.

Tagging plugin files on z/OS

When Zowe App Framework is installed on z/OS developers should tag their plugin files according to the file content. Tagging files helps programs on z/OS understand how to interpret those files, most importantly to know whether a file is encoded using EBCDIC (Extended Binary Coded Decimal Interchange Code). If you are unsure if a plugin you are using is tagged, it can be checked and set using the `chtag` command. If you want to set the tags, it can be done in bulk with the help of these programs:

- Autotag: This free, open-source application is not part of Zowe. You can download the binary from here for example https://anaconda.org/izoda/autotag. Source: https://github.com/RocketSoftware/autotag
- The Zowe tagging script: This script tags by file extension. It might not work for all cases, but can be altered to suit your needs. Source: https://github.com/zowe/zowe-install-packaging/blob/master/scripts/tag-files.sh

Building Javascript content (*.js files)

Unlike Typescript, Javascript is an interpreted language and does not need to be built. In most cases, reloading the page should build new code changes. For Iframes or other JS-based apps, close and open the app.

Installing

Follow the steps described in Installing Plugins on page 247 to add your built plugin to the Zowe desktop.

Packaging

For more information on how to package your Zowe app, developers can see Plug-ins definition and structure on page 243.

Installing Plugins

Plugins can be added or removed from the Zowe App Server, as well as upgraded. There are two ways to do these actions: By REST API or by filesystem. The instructions below assume you have administrative permissions either to access the correct REST APIs or to have the necessary permissions to update server directories & files.
NOTE: To successfully install, you must pre-build plugins with the correct directory structure, and meet all dependencies. If a plugin has successfully installed but does not display in the Zowe desktop, see the server log in the `<INSTANCE_DIR>/log/install-app.log` directory (for example, `~/.zowe/log/install-app.log`) to troubleshoot the problem.

**By filesystem**

The App server uses directories of JSON files, described in the wiki. Defaults are located in the folder `zlux-app-server/defaults/plugins`, but the server reads the list of plugins instead from the instance directory, at `<INSTANCE_DIR>/workspace/app-server/plugins` (for example, `~/.zowe/workspace/app-server/plugins` which includes JSON files describing where to find a plugin. Adding or removing JSONs from this folder will add or remove plugins upon server restart, or you can use REST APIs and cluster mode to add or remove plugins without restarting).

**Old plugins folder**

Prior to Zowe release 1.8.0, the location of the default and instance plugins directory were located within `zlux-app-server` folder unless otherwise customized. 1.8.0 has backwards compatibility for the existence of these directories, but they can and should be migrated to take advantage of future enhancements.

<table>
<thead>
<tr>
<th>Folder</th>
<th>New Location</th>
<th>Old Location</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default plugins</td>
<td>zlux-app-server/defaults/plugins</td>
<td>zlux-app-server/plugins</td>
<td>INSTANCE_DIR is defined</td>
</tr>
<tr>
<td>Instance plugins</td>
<td>&lt;INSTANCE_DIR&gt;/workspace/app-server/plugins</td>
<td>instance/ZLUX/plugins</td>
<td>~/.zowe if not otherwise defined</td>
</tr>
</tbody>
</table>

**Adding/Installing**

To add or install a plugin, run the script `zlux-app-server/bin/install-app.sh` providing the location to a plugin folder. For example:

```
./install-app.sh /home/john/zowe/sample-angular-app
```

This will generate a JSON file that states the plugin's ID and its location on disk. These JSON files tell the Desktop where to find apps. For example, if we were to install the sample angular-app in the folder `/home/john/zowe/sample-angular-app`, then the JSON would be:

```
{
  "identifier": "org.zowe.zlux.sample.angular",
  "location": "/home/john/zowe/sample-angular-app"
}
```

**Removing**

To remove a plugin, locate the server's instance plugin directory `<INSTANCE_DIR>/workspace/app-server/plugins` (for example, `~/.zowe/workspace/app-server/plugins`) and remove the locator JSON that is associated with that plugin. Remove the plugin's content by deleting it from the file system if applicable.

**Upgrading**

Currently, only one version of a plugin can exist per server. So, to upgrade, you either upgrade the plugin within its pre-existing directory by rebuilding it (with more up to date code), or you alter the locator JSON of that app to point to the content of the upgraded version.

**Modifying without server restart (Exercise to the reader)**

The server's reading of the locator JSONs and initializing of plugins only happens during bootstrapping at startup. However, in cluster mode the bootstrapping happens once per worker process. Therefore, it is possible to manage plugins without a server restart by killing & respawning all worker processes without killing the cluster master.
process. This is what the REST API does, internally. To do this without the REST API, it may be possible to script
knowing the parent process ID, and running a kill command on all child processes of the App server cluster process.

**By REST API**

The server REST APIs allow plugin management without restarting the server - you can add, remove, and upgrade
plugins in real-time. However, removal or upgrade must be done carefully as it can disrupt users of those plugins.

This swagger file documents the REST API for plugin management

The API only works when RBAC is configured, and an RBAC-compatible security plugin is being used. An example
of this is *zss-auth*, and use of RBAC is described in this documentation and in the wiki.

**Embedding plugins**

Add these imports to a component where you want to embed another plugin:

```ts
import {Inject, Injector, ViewChild, ViewContainerRef} from '@angular/core';
import {Angular2InjectionTokens, Angular2PluginEmbedActions, EmbeddedInstance} from 'pluginlib/inject-resources';
```

Inject Angular2PluginEmbedActions into your component constructor:

```ts
constructor(@Inject(Angular2InjectionTokens.PLUGIN_EMBED_ACTIONS) private embedActions: Angular2PluginEmbedActions) {
}
```

In the component template prepare a container where you want to embed the plugin:

```html
<div class="container-for-embedded-window">
  <ng-container #embedded></ng-container>
</div>
```

In the component class add a reference to the container:

```ts
@ViewChild('embedded', {read: ViewContainerRef}) viewContainerRef: ViewContainerRef;
```

In the component class add a reference to the embedded instance:

```ts
private embeddedInstance: EmbeddedInstance;
```
Everything is ready to start embedding, you just need to know the pluginId that you want to embed:

```typescript
app.component.ts

embedPlugin(): void {
  const pluginId = 'org.zowe.zlux.sample.angular';
  const launchMetadata = null;
  this.embedActions.createEmbeddedInstance(pluginId, launchMetadata,
      this.viewContainerRef)
    .then(embeddedInstance => this.embeddedInstance = embeddedInstance)
    .catch(e => console.error(`couldn't embed plugin ${pluginId} because
 ${e}`));
}
```

**How to interact with embedded plugin**

If the main component of embedded plugin declares Input and Output properties then you can interact with it. ApplicationManager provides methods to set Input properties and get Output properties of the embedded plugin. Suppose, that the embedded plugin declares Input and Output properties like this:

```typescript
plugin.component.ts

@Input() sampleInput: string;
@Output() sampleOutput: EventEmitter<string> = new
  EventEmitter<string>();
```

Obtain a reference to AppicationManager in your component constructor:

```typescript
app.component.ts

private applicationManager: MVDHosting.ApplicationManagerInterface;
constructor(
    @Inject(Angular2InjectionTokens.PLUGIN_EMBED_ACTIONS) private
      embedActions: Angular2PluginEmbedActions,
    // @Inject(MVDHosting.Tokens.ApplicationManagerToken) private
      applicationManager: MVDHosting.ApplicationManagerInterface
        injector: Injector
        ) {
      this.applicationManager =
          this.injector.get(MVDHosting.Tokens.ApplicationManagerToken);
    }
```

*Note: We are unable to inject ApplicationManager with @Inject() until an AoT-compiler issue with namespaces is resolved: [angular/angular#15613](https://angular.io/)*

Now you can set `sampleInput` property, obtain `sampleOutput` property and subscribe to it:

```typescript
app.component.ts

this.applicationManager.setEmbeddedInstanceInput(this.embeddedInstance,
    'sampleInput', 'some value');

    const sampleOutput: Observable<string> =
        this.applicationManager.getEmbeddedInstanceOutput(this.embeddedInstance,
        'sampleOutput');
    sampleOutput.subscribe(value => console.log(`get new value ${value} from
 ${sampleOutput}`));
```
How to destroy embedded plugin

There is no special API to destroy embedded plugin. If you want to destroy the embedded plugin just clear the container for the embedded plugin and set `embeddedInstance` to `null`:

```typescript
app.component.ts
this.viewContainerRef.clear();
this.embeddedInstance = null;
```

How to style a container for the embedded plugin

It is hard to give a universal recipe for a container style. At least, the container needs `position: "relative"` because the embedded plugin may have absolutely positioned elements. Here is sample styles you can start with if your component utilizes flexbox layout:

```css
app.component.css
.container-for-embedded-window {
    position: relative;
    flex: 1 1 auto;
    align-self: stretch;
    display: flex;
    flex-direction: column;
    align-items: stretch;
}
```

Applications that use embedding

Workflow app demonstrates advanced usage.

Dataservices

Dataservices are dynamic backend components of Zowe™ plug-in applications. You can optionally add them to your applications to make the application do more than receive static content from the proxy server. Each dataservice defines a URL space that the server can use to run extensible code from the application. Dataservices are mainly intended to create REST APIs and WebSocket channels.

Defining dataservices

You define dataservices in the application's `pluginDefinition.json` file. Each application requires a definition file to specify how the server registers and uses the application's backend. You can see an example of a `pluginDefinition.json` file in the top directory of the sample-angular-app.

In the definition file is a top level attribute called `dataServices`, for example:

```json
"dataServices": [
    {
        "type": "router",
        "name": "hello",
        "serviceLookupMethod": "external",
        "fileName": "helloWorld.js",
        "routerFactory": "helloWorldRouter",
        "dependenciesIncluded": true
    }
]
```

To define your dataservice, create a set of keys and values for your dataservice in the `dataservices` array. The following values are valid:
**type**

Specify one of the following values:

- **router**: Router dataservices run under the proxy server and use ExpressJS Routers for attaching actions to URLs and methods.
- **service**: Service dataservices run under ZSS and utilize the API of ZSS dataservices for attaching actions to URLs and methods.
- **java-war**: See the topic *Defining Java dataservices* below.

**name**

The name of the service. Names must be unique within each `pluginDefinition.json` file. The name is used to reference the dataservice during logging and to construct the URL space that the dataservice occupies.

**serviceLookupMethod**

Specify `external` unless otherwise instructed.

**fileName**

The name of the file that is the entry point for construction of the dataservice, relative to the application's `/lib` directory. For example, for the `sample-app` the `fileName` value is `"helloWorld.js"` - without a path. So its typescript code is transpiled to JavaScript files that are placed directly into the `/lib` directory.

**routerFactory (Optional)**

When you use a router dataservice, the dataservice is included in the proxy server through a `require()` statement. If the dataservice's exports are defined such that the router is provided through a factory of a specific name, you must state the name of the exported factory using this attribute.

**dependenciesIncluded**

Specify `true` for anything in the `pluginDefinition.json` file. Only specify `false` when you are adding dataservices to the server dynamically.

### Defining Java dataservices

In addition to other types of dataservice, you can use Java (also called `java-war`) dataservices in your applications. Java dataservices are powered by Java Servlets.

To use a Java dataservice you must meet the prerequisites, define the dataservice in your plug-in definition, and define the Java Application Server library to the Zowe Application Server.

**Prerequisites**

- Install a Java Application Server library. In this release, Tomcat is the only supported library.
- Make sure your plug-in's compiled Java program is in the application's `/lib` directory, in either a `.war` archive file or a directory extracted from a `.war` archive file. Extracting your file is recommended for faster start-up time.

**Defining Java dataservices**

To define the dataservice in the `pluginDefinition.json` file, specify the type as `java-war`, for example:

```json
"dataServices": [
    {
        "type": "java-war",
        "name": "javaservlet",
        "filename": "javaservlet.war",
        "dependenciesIncluded": true,
        "initializerLookupMethod": "external",
        "version": "1.0.0"
    }
],
```
To access the service at runtime, the plug-in can use the Zowe dataservice URL standard: /ZLUX/plugins/[PLUGINID]/services/[SERVICENAME]/[VERSIONNUMBER]

Using the example above, a request to get users might be: /ZLUX/plugins/[PLUGINID]/services/javaservlet/1.0.0/users

**Note:** If you extracted your servlet contents from a .war file to a directory, the directory must have the same name as the file would have had. Using the example above, javaservlet.war must be extracted to a directory named javaservlet.

### Defining Java Application Server libraries

In the zlux-app-server/zluxserver.json file, use the example below to specify Java Application Server library parameters:

```json
"languages": {
  "java": {
    "runtimes": {
      "name": {
        "home": "<java_runtime_root_path>"
      }
    }
  },
  "war": {
    "defaultGrouping": "<value>"
  }
}
"javaAppServer": {
  "type": "tomcat",
  "path": "../../zlux-server-framework/lib/java/apache-tomcat",
  "config": "../deploy/instance/ZLUX/serverConfig/tomcat.xml",
  "https": {
    "key": "../deploy/product/ZLUX/serverConfig/zlux.keystore.key",
    "certificate": "../deploy/product/ZLUX/serverConfig/zlux.keystore.cer"
  }
},
"portRange": [8545, 8600]
}
```

Specify the following parameters in the languages.java object:

- **runtimes (object)** - The name and location of a Java runtime that can be used by one or more services. Used to load a Tomcat instance.
  - **name (object)** - The name of the runtime.
    - **home (string)** - The path to the runtime root. Must include /bin and /lib directories.
  - **ports (array<number>)(Optional)** - An array of port numbers that can be used by instances of Java Application Servers or microservices. Must contain as many ports as distinct servers that will be spawned, which is defined by other configuration values within languages.java. Either ports or portRange is required, but portRange has a higher priority.
  - **portRange (array<number>)(Optional)** - An array of length 2, which contains a start number and end number to define a range of ports to be used by instances of application servers or microservices. You will need as many ports as distinct servers that will be spawned, which is defined by other configuration values within languages.java. Either ports or portRange is required, but portRange has a higher priority.
• **war** (object) - Defines how the Zowe Application Server should handle `java-war` dataservices.
  
  • **defaultGrouping** (string)(Optional) - Defines how services should be grouped into instances of Java Application Servers. Valid values: appserver or microservice. Default: appserver. appserver means 1 server instance for all services, microservice means one server instance per service.
  
  • **pluginGrouping** (array<object>)(Optional) - Defines groups of plug-ins to have their `java-war` services put within a single Java Application Server instance.
    
    • **plugins** (Array<string>) - Lists the plugins by identifier which should be put into this group. Plug-ins with no `java-war` services are skipped. Being in a group excludes a plugin from being handled by `defaultGrouping`.
    
    • **runtime** (string)(Optional) - States the runtime to be used by the Tomcat server instance, as defined in `languages.java.runtimes`.
  
  • **javaAppServer** (object) - Java Application Server properties.
    
    • **type** (string) - Type of server. In this release, **tomcat** is the only valid value.
    
    • **path** (string) - Path of the server root, relative to `zlux-app-server/lib`. Must include `/bin` and `/lib` directories.
    
    • **config** (string) - Path of the server configuration file, relative to `zlux-app-server/lib`.
    
    • **https** (object) - HTTPS parameters.
      
      • **key** (string) - Path of a private key, relative to `zlux-app-server/lib`.
      
      • **certificate** (string) - Path of an HTTPS certificate, relative to `zlux-app-server/lib`.

**Java dataservice logging**

The Zowe Application Server creates the Java Application Server instances required for the `java-war` dataservices, so it logs the stdout and stderr streams for those processes in its log file. Java Application Server logging is not managed by Zowe at this time.

**Java dataservice limitations**

Using Java dataservices with a Zowe Application Server installed on a Windows computer, the source and Java dataservice code must be located on the same storage volume.

To create multiple instances of Tomcat on non-Windows computers, the Zowe Application Server establishes symbolic links to the service logic. On Windows computers, symbolic links require administrative privilege, so the server establishes junctions instead. Junctions only work when the source and destination reside on the same volume.

**Using dataservices with RBAC**

If your administrator configures the Zowe Application Framework to use role-based access control (RBAC), then when you create a dataservice you must consider the length of its paths.

To control access to dataservices, administrators can enable RBAC, then use a z/OS security product such as RACF to map roles and authorities to a System Authorization Facility (SAF) profile. For information on RBAC, see Applying role-based access control to dataservices.

SAF profiles have the following format:

```
<product>.<instance id>.SVC.<pluginid_with_underscores>.<service>.<HTTP method>.<dataservice path with forward slashes '/' replaced by periods '.'>
```

For example, to access this dataservice endpoint:

```
/ZLUX/plugins/org.zowe.foo/services/baz/_current/users/fred
```

Users must have READ access to the following profile:

```
ZLUX.DEFAULT.SVC.ORG_ZOWE_FOO.BAZ.POST.USERS.FRED
```

Profiles cannot contain more than 246 characters. If the path section of an endpoint URL makes the profile name exceed limit, the path is trimmed to only include elements that do not exceed the limit. For example, imagine that each path section in this endpoint URL contains 64 characters:
/ZLUX/plugins/org.zowe.zossystem.subsystems/services/data/_current/aa..a/ bb..b/cc..c/dd..d

So aa..a is 64 "a" characters, bb..b is 64 "b" characters, and so on. The URL could then map to the following example profile:

ZLUX.DEFAULT.SVC.ORG_ZOWE_ZOSSYSTEM_SUBSYSTEMS.DATA.GET.AA..A.BB..B

The profile ends at the BB..B section because adding CC..C would put it over 246 characters. So in this example, all dataservice endpoints with paths that start with AA..A.BB..B are controlled by this one profile.

To avoid this issue, we recommend that you maintain relatively short endpoint URL paths.

**Dataservice APIs**

Dataservice APIs can be categorized as Router-based or ZSS-based, and either WebSocket or not.

**Router-based dataservices**

Each Router dataservice can safely import Express, express-ws, and bluebird without requiring the modules to be present, because these modules exist in the proxy server's directory and the NODE_MODULES environment variable can include this directory.

**HTTP/REST Router dataservices**

Router-based dataservices must return a (bluebird) Promise that resolves to an ExpressJS router upon success. For more information, see the ExpressJS guide on use of Router middleware: Using Router Middleware.

Because of the nature of Router middleware, the dataservice need only specify URLs that stem from a root '/' path, as the paths specified in the router are later prepended with the unique URL space of the dataservice.

The Promise for the Router can be within a Factory export function, as mentioned in the pluginDefinition specification for routerFactory above, or by the module constructor.

An example is available in sample-app/nodeServer/ts/helloWorld.ts

**WebSocket Router dataservices**

ExpressJS routers are fairly flexible, so the contract to create the Router for WebSockets is not significantly different.

Here, the express-ws package is used, which adds WebSockets through the ws package to ExpressJS. The two changes between a WebSocket-based router and a normal router are that the method is 'ws', as in router.ws(<url>,<callback>), and the callback provides the WebSocket on which you must define event listeners.

See the ws and express-ws topics on www.npmjs.com for more information about how they work, as the API for WebSocket router dataservices is primarily provided in these packages.

An example is available in zlux-server-framework/plugins/terminal-proxy/lib/terminalProxy.js

**Router dataservice context**

Every router-based dataservice is provided with a Context object upon creation that provides definitions of its surroundings and the functions that are helpful. The following items are present in the Context object:

**serviceDefinition**

The dataservice definition, originally from the pluginDefinition.json file within a plug-in.

**serviceConfiguration**

An object that contains the contents of configuration files, if present.

**logger**

An instance of a Zowe Logger, which has its component name as the unique name of the dataservice within a plug-in.

**makeSublogger**
A function to create a Zowe Logger with a new name, which is appended to the unique name of the dataservice.

**addBodyParseMiddleware**

A function that provides common body parsers for HTTP bodies, such as JSON and plaintext.

**plugin**

An object that contains more context from the plug-in scope, including:

- **pluginDef**: The contents of the `pluginDefinition.json` file that contains this dataservice.
- **server**: An object that contains information about the server's configuration such as:
  - **app**: Information about the product, which includes the `productCode` (for example: `ZLUX`).
  - **user**: Configuration information of the server, such as the port on which it is listening.

**Documenting dataservices**

It is recommended that you document your RESTful application dataservices in OpenAPI (Swagger) specification documents. The Zowe Application Server hosts Swagger files for users to view at runtime.

To document a dataservice, take the following steps:

1. Create a `.yaml` or `.json` file that describes the dataservice in valid Swagger 2.0 format. Zowe validates the file at runtime.
2. Name the file with the same name as the dataservice. Optionally, you can include the dataservice version number in the format: `<name>_<number>`. For example, a Swagger file for a dataservice named `user` must be named either `users.yaml` or `users_1.1.0.yaml`.
3. Place the Swagger file in the `/doc/swagger` directory below your application plug-in directory, for example:

```
/zlux-server-framework/plugins/<servicename>/doc/swagger/<servicename_1.1.0>.yaml
```

At runtime, the Zowe Application Server does the following:

- Dynamically substitutes known values in the files, such as the hostname and whether the endpoint is accessible using HTTP or HTTPS.
- Builds documentation for each dataservice and for each application plug-in, in the following locations:
  - Dataservice documentation: `/ZLUX/plugins/<app_name>/catalogs/swagger/servicename`
  - Application plug-in documentation: `/ZLUX/plugins/<app_name>/catalogs/swagger`
- In application plug-in documentation, displays only stubs for undocumented dataservices, stating that the dataservice exists but showing no details. Undocumented dataservices include non-REST dataservices such as WebSocket services.

**Authentication API**

This topic describes the web service API for user authentication.

The authentication mechanism of the ZLUX server allows for an administrator to gate access to services by a given auth handler, while on the user side the authentication structure allows for a user to login to one or more endpoints at once provided they share the same credentials given.

**Check status**

Returns the current authentication status of the user to the caller.

```
GET /auth
```

Response example:

```json
{
    "categories": {
        "zss": {
```
Every key in the response object is a registered auth type. The value object is guaranteed to have a Boolean field named "authenticated" which indicates that at least one plugin in the category was able to authenticate the user.

Each item also has a field called "plugins", where every property value is a plugin-specific object.

**Authenticate**

Authenticates the user against authentication back-ends.

**POST /auth**

Request body example:

```json
{
    "categories": ["zosmf"],
    "username": "foo",
    "password": "1970-01-01"
}
```

The categories parameter is optional. If omitted, all auth plugins are invoked with the username and password.

Response example:

```json
{
    "success": true,
    "categories": {
        "zss": {
            "success": true,
            "plugins": {
                "org.zowe.zlux.auth.zss": {
                    "success": true
                }
            }
        },
        "zosmf": {
            "success": true,
            "plugins": {
                "org.zowe.zlux.auth.zosmf": {
                    "success": true
                }
            }
        }
    }
}
```
First-level keys are authentication categories or types. "success" means that all of the types requested have been successful. For example typeA successful AND typeB succesful AND ...

Second-level keys are auth plugin IDs. "success" on this level means that there's at least one successful result in that auth type. For example, pluginA successful OR pluginB successful OR ...

**User not authenticated or not authorized**

The response received by the browser when calling any service, when the user is either not authenticated or not allowed to access the service.

**Not authenticated**

HTTP 401

```json
{
    "category": "zss",
    "pluginID": "org.zowe.zlux.auth.zss",
    "result": {
        "authenticated": false,
        "authorized": false
    }
}
```

The client is supposed to address this by showing the user a login form which will later invoke the login service for the plugin mentioned and repeat the request.

**Not authorized**

HTTP 403

```json
{
    "category": "zss",
    "pluginID": "org.zowe.zlux.auth.zss",
    "result": {
        "authenticated": true,
        "authorized": false
    }
}
```

There's no general way for the client to address this, except than show the user an error message.

**Internationalizing applications**

You can internationalize Zowe application plug-ins using Angular and React frameworks. Internationalized applications display in translated languages and include structures for ongoing translation updates.

The steps below use the Zowe Sample Angular Application and Zowe Sample React Application as examples. Your applications might have slightly different requirements, for example the React Sample Application requires the react-i18next library, but your application might require a different React library.

For detailed information on Angular or React, see their documentation. For detailed information on specific internationalization libraries, see their documentation. You can also reference the Sample Angular Application internationalization tutorial, and watch a video on how to internationalize your Angular application.

After you internationalize your application, you can view it by following steps in Changing the desktop language on page 161.

**Internationalizing Angular applications**

Zowe applications that use the Angular framework depend on .xlf formatted files to store static translated content and .json files to store dynamic translated content. These files must be in the application's web/assets/i18n folder at runtime. Each translated language will have its own file.
To internationalize an application, you must install Angular-compatible internationalization libraries. Be aware that libraries can be better suited to either static or dynamic HTML elements. The examples in this task use the ngx-i18nsupport library for static content and angular-l10n for dynamic content.

To internationalize Zowe Angular applications, take the following steps:

1. To install internationalization libraries, use the npm command, for example:

```
npm install --save-dev ngx-i18nsupport
npm install --save-dev angular-l10n
```

**Note** --save-dev commits the library to the application's required libraries list for future use.

2. To support the CLI tools and to control output, create a `webClient/tsconfig.i18n.json` typescript file and add the following content:

```json
{
    "extends": "../../zlux-app-manager/virtual-desktop/plugin-config/tsconfig.ngx-i18n.json",
    "include": ["./src"],
    "compilerOptions": {
        "outDir": "../src/assets/i18n",
        "skipLibCheck": true
    }
}
```

For example, see this file in the Sample Angular Application.

3. In the static elements in your HTML files, tag translatable content with the i18n attribute within an Angular template, for example:

```html
<div>
  <p i18n="welcome message@@welcome">Welcome</p>
</div>
```

The attribute should include a message ID, for example the @@welcome above.

4. To configure static translation builds, take the following steps:

   a. In the `webClient/package.json` script, add the following line:

```
"i18n": "ng-xl18n -p tsconfig.i18n.json --i18nFormat=xlf -- outFile=messages.xlf && xliffmerge -p xliffmerge.json",
```

   b. In the in `webClient` directory, create a `xliffmerge.json` file, add the following content, and specify the codes for each language you will translate in the `languages` parameter:

```json
{
   "xliffmergeOptions": {
       "srcDir": "src/assets/i18n",
       "genDir": "src/assets/i18n",
       "i18nFile": "messages.xlf",
       "i18nBaseFile": "messages",
       "i18nFormat": "xlf",
       "encoding": "UTF-8",
       "defaultLanguage": "en",
       "languages": ["fr","ru"],
       "useSourceAsTarget": true
   }
}
```
When you run the i18n script, it reads this file and generates a messages.[lang].xlf file in the src/assets/i18n directory for each language specified in the languages parameter. Each file contains the untranslated text from the i18n-tagged HTML elements.

5. Run the following command to run the i18n script and extract i18n tagged HTML elements to .xlf files:

```
npm run i18n
```

**Note** If you change static translated content, you must run the `npm run build` command to build the application, and then re-run the `npm run i18n` command to extract the tagged content again.

6. In each .xlf file, replace target element strings with translated versions of the source element strings. For example:

```
<source>App Request Test</source>
<target>Test de Demande à l'App</target>
```

7. Run the following command to rebuild the application:

```
npm run build
```

When you **Changing the desktop language** on page 161 to one of the application's translated languages, the application displays the translated strings.

8. For dynamic translated content, follow these steps:

a. Import and utilize angular-l10n objects within an Angular component, for example:

```typescript
import { LocaleService, TranslationService, Language } from 'angular-l10n';
Component({
    selector: 'app-root',
    templateUrl: './app.component.html',
    styleUrls: ['./app.component.css'],
    providers: [HelloService]
})

export class AppComponent {
    @Language() lang: string;

    public myDynamicMessage: string = '';

    constructor(
        public locale: LocaleService,
        public translation: TranslationService)
    {
    }

    sayHello() {
        this.myDynamicMessage = `  
        ${this.translation.translate('my_message')};
    }
}
```

b. In the related Angular template, you can implement `myDynamicMessage` as an ordinary substitutable string, for example:

```html
<div>
    <textarea class="response" placeholder="Response" i18n-placeholder="@myStaticPlaceholder">{{myDynamicMessage}}</textarea>
</div>
```
9. Create logic to copy the translation files to the `web/assets` directory during the webpack process, for example in the sample application, the following JavaScript in the `copy-webpack-plugin` file copies the files:

```javascript
var config = {
  'entry': [
    path.resolve(__dirname, './src/plugin.ts')
  ],
  'output': {
    'path': path.resolve(__dirname, '../web'),
    'filename': 'main.js',
  },
  'plugins': [
    new CopyWebpackPlugin([{
      from: path.resolve(__dirname, './src/assets'),
      to: path.resolve('../web/assets')
    }])
  ]
};
```

**Note:** Do not edit files in the `web/assets/i18n` directory. They are overwritten by each build.

**Internationalizing React applications**

To internationalize Zowe applications using the React framework, take the following steps:

**Note:** These examples use the recommended `react-i18next` library, which does not differentiate between dynamic and static content, and unlike the Angular steps above does not require a separate build process.

1. To install the React library, run the following command:

   ```sh
npm install --save-dev react-i18next
   ```

2. In the directory that contains your `index.js` file, create an `i18n.js` file and add the translated content, for example:

   ```javascript
   import i18n from "i18next";
   import { initReactI18next } from "react-i18next";

   // the translations
   // (tip move them in a JSON file and import them)
   const resources = {
     en: {
       translation: {
         "Welcome to React": "Welcome to React and react-i18next"
       }
     }
   };

   i18n
     .use(initReactI18next) // passes i18n down to react-i18next
     .init({
       resources,
       lng: "en",
       interpolation: {
         escapeValue: false, // react already safes from xss
         keySeparator: false, // we do not use keys in form messages.welcome
       }
     });

   export default i18n;
   ```
3. Import the i18n file from the previous step into index.js file so that you can use it elsewhere, for example:

```javascript
import React, { Component } from "react";
import ReactDOM from "react-dom";
import './i18n';
import App from './App';
// append app to dom
ReactDOM.render(
  <App />,
  document.getElementById("root")
);  
```

4. To internationalize a component, include the `useTranslation` hook and reference it to substitute translation keys with their translated values. For example:

```javascript
import React from 'react';
// the hook
import { useTranslation } from 'react-i18next';
function MyComponent () {
  const { t, i18n } = useTranslation(); // use
  return <h1>{t('Welcome to React')}</h1>
}
```

**Internationalizing application desktop titles**

To display the translated application name and description in the Desktop, take the following steps:

1. For each language, create a `pluginDefinition.i18n.<lang_code>.json` file. For example, for German create a `pluginDefinition.i18n.de.json` file.
2. Place the `.json` files in the `web/assets/i18n` directory.
3. Translate the `pluginShortNameKey` and `descriptionKey` values in the application's `pluginDefinition.json` file. For example, for the file below you would translate the values "sampleangular" and "sampleangulardescription":

```json
{
  "identifier": "org.zowe.zlux.sample.angular",
  "apiVersion": "1.0.0",
  "pluginVersion": "1.1.0",
  "pluginType": "application",
  "webContent": {
    "framework": "angular2",
    "launchDefinition": {
      "pluginShortNameKey": "sampleangular",
      "pluginShortNameDefault": "Angular Sample",
      "imageSrc": "assets/icon.png"
    },
    "descriptionKey": "sampleangulardescription",
    "descriptionDefault": "Sample App Showcasing Angular Adapter"
  }
}
```

4. Add the translated values to the translation file. For example, the German translation file example, `pluginDefinition.i18n.de.json`, would look like this:

```json
{
  "sampleangular": "Beispiel Angular",
  "sampleangulardescription": "Beispiel Angular Anwendung"
}
```
5. Create logic to copy the translation files to the `web/assets` directory during the webpack process. For example, in the Sample Angular Application the following JavaScript in the `webClient/webpack.config.js` file copies files to the `web/assets` directory:

```javascript
var config = {
  'entry': [
    path.resolve(__dirname, './src/plugin.ts')
  ],
  'output': {
    'path': path.resolve(__dirname, '../web'),
    'filename': 'main.js',
  },
  'plugins': [
    new CopyWebpackPlugin(
      {
        from: path.resolve(__dirname, './src/assets'),
        to: path.resolve('../web/assets')
      }
    )
  ]
};
```

Zowe Desktop and window management

The Zowe™ Desktop is a web component of Zowe, which is an implementation of MVDWindowManagement, the interface that is used to create a window manager.

The code for this software is in the `zlux-app-manager` repository.

The interface for building an alternative window manager is in the `zlux-platform` repository.

Window Management acts upon Windows, which are visualizations of an instance of an application plug-in. Application plug-ins are plug-ins of the type "application", and therefore the Zowe Desktop operates around a collection of plug-ins.

**Note:** Other objects and frameworks that can be utilized by application plug-ins, but not related to window management, such as application-to-application communication, Logging, URI lookup, and Auth are not described here.

Loading and presenting application plug-ins

Upon loading the Zowe Desktop, a GET call is made to `/plugins?type=application`. The GET call returns a JSON list of all application plug-ins that are on the server, which can be accessed by the user. Application plug-ins can be composed of dataservices, web content, or both. Application plug-ins that have web content are presented in the Zowe Desktop UI.

The Zowe Desktop has a taskbar at the bottom of the page, where it displays each application plug-in as an icon with a description. The icon that is used, and the description that is presented are based on the application plug-in's PluginDefinition's webContent attributes.

Plug-in management

Application plug-ins can gain insight into the environment in which they were spawned through the Plugin Manager. Use the Plugin Manager to determine whether a plug-in is present before you act upon the existence of that plug-in. When the Zowe Desktop is running, you can access the Plugin Manager through `ZoweZLUX.PluginManager`

The following are the functions you can use on the Plugin Manager:

- `getPlugin(pluginID: string)`
  - Accepts a string of a unique plug-in ID, and returns the Plugin Definition Object (DesktopPluginDefinition) that is associated with it, if found.
Application management

Application plug-ins within a Window Manager are created and acted upon in part by an Application Manager. The Application Manager can facilitate communication between application plug-ins, but formal application-to-application communication should be performed by calls to the Dispatcher. The Application Manager is not normally directly accessible by application plug-ins, instead used by the Window Manager.

The following are functions of an Application Manager:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spawnApplication(plugin: DesktopPluginDefinition, launchMetadata: any): Promise&lt;MVDHosting.InstanceId&gt;;</td>
<td>Opens an application instance into the Window Manager, with or without context on what actions it should perform after creation.</td>
</tr>
<tr>
<td>killApplication(plugin:ZLUX.Plugin, appId:MVDHosting.InstanceId): void;</td>
<td>Removes an application instance from the Window Manager.</td>
</tr>
<tr>
<td>showApplicationWindow(plugin: DesktopPluginDefinitionImpl): void;</td>
<td>Makes an open application instance visible within the Window Manager.</td>
</tr>
<tr>
<td>isApplicationRunning(plugin: DesktopPluginDefinitionImpl): boolean;</td>
<td>Determines if any instances of the application are open in the Window Manager.</td>
</tr>
</tbody>
</table>

Windows and Viewports

When a user clicks an application plug-in's icon on the taskbar, an instance of the application plug-in is started and presented within a Viewport, which is encapsulated in a Window within the Zowe Desktop. Every instance of an application plug-in's web content within Zowe is given context and can listen on events about the Viewport and Window it exists within, regardless of whether the Window Manager implementation utilizes these constructs visually. It is possible to create a Window Manager that only displays one application plug-in at a time, or to have a drawer-and-panel UI rather than a true windowed UI.

When the Window is created, the application plug-in's web content is encapsulated dependent upon its framework type. The following are valid framework types:

- "angular2": The web content is written in Angular, and packaged with Webpack. Application plug-in framework objects are given through @injectables and imports.
- "iframe": The web content can be written using any framework, but is included through an iframe tag. Application plug-ins within an iframe can access framework objects through `parent.RocketMVD` and callbacks.

In the case of the Zowe Desktop, this framework-specific wrapping is handled by the Plugin Manager.

Viewport Manager

Viewports encapsulate an instance of an application plug-in's web content, but otherwise do not add to the UI (they do not present Chrome as a Window does). Each instance of an application plug-in is associated with a viewport, and operations to act upon a particular application plug-in instance should be done by specifying a viewport for an application plug-in, to differentiate which instance is the target of an action. Actions performed against viewports should be performed through the Viewport Manager.

The following are functions of the Viewport Manager:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>createViewport(providers: ResolvedReflectiveProvider[]): MVDHosting.ViewportId;</td>
<td>Creates a viewport into which an application plug-in's webcontent can be embedded.</td>
</tr>
<tr>
<td>registerViewport(viewportId: MVDHosting.ViewportId, instanceId: MVDHosting.InstanceId): void;</td>
<td>Registers a previously created viewport to an application plug-in instance.</td>
</tr>
</tbody>
</table>
### Function

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>destroyViewport(viewportId: MVDHosting.ViewportId): void;</td>
<td>Removes a viewport from the Window Manager.</td>
</tr>
<tr>
<td>getApplicationInstanceId(viewportId: MVDHosting.ViewportId): MVDHosting.InstanceId</td>
<td>Returns the ID of an application plug-in's instance from within a viewport within the Window Manager.</td>
</tr>
</tbody>
</table>

### Injection Manager

When you create Angular application plug-ins, they can use injectables to be informed of when an action occurs. iframe application plug-ins indirectly benefit from some of these hooks due to the wrapper acting upon them, but Angular application plug-ins have direct access.

The following topics describe injectables that application plug-ins can use.

#### Plug-in definition

```typescript
@Inject(Angular2InjectionTokens.PLUGIN_DEFINITION) private pluginDefinition: ZLUX.ContainerPluginDefinition
```

Provides the plug-in definition that is associated with this application plug-in. This injectable can be used to gain context about the application plug-in. It can also be used by the application plug-in with other application plug-in framework objects to perform a contextual action.

#### Logger

```typescript
@Inject(Angular2InjectionTokens.LOGGER) private logger: ZLUX.ComponentLogger
```

Provides a logger that is named after the application plug-in's plugin definition ID.

#### Launch Metadata

```typescript
@Inject(Angular2InjectionTokens.LAUNCH_METADATA) private launchMetadata: any
```

If present, this variable requests the application plug-in instance to initialize with some context, rather than the default view.

#### Viewport Events

```typescript
@Inject(Angular2InjectionTokens.VIEWPORT_EVENTS) private viewportEvents: Angular2PluginViewportEvents
```

Presents hooks that can be subscribed to for event listening. Events include:

- resized: Subject<{width: number, height: number}>: Fires when the viewport's size has changed.

#### Window Events

```typescript
@Inject(Angular2InjectionTokens.WINDOW_ACTIONS) private windowActions: Angular2PluginWindowActions
```

Presents hooks that can be subscribed to for event listening. The events include:

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>maximized: Subject&lt;void&gt;</td>
<td>Fires when the Window is maximized.</td>
</tr>
<tr>
<td>minimized: Subject&lt;void&gt;</td>
<td>Fires when the Window is minimized.</td>
</tr>
</tbody>
</table>
### Event

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>restored: Subject&lt;void&gt;</td>
<td>Fires when the Window is restored from a minimized state.</td>
</tr>
<tr>
<td>moved: Subject&lt;{top: number, left: number}&gt;</td>
<td>Fires when the Window is moved.</td>
</tr>
<tr>
<td>resized: Subject&lt;{width: number, height: number}&gt;</td>
<td>Fires when the Window is resized.</td>
</tr>
<tr>
<td>titleChanged: Subject&lt;string&gt;</td>
<td>Fires when the Window's title changes.</td>
</tr>
</tbody>
</table>

### Window Actions

```typescript
@Inject(Angular2InjectionTokens.WINDOW_ACTIONS) private windowActions: Angular2PluginWindowActions
```

An application plug-in can request actions to be performed on the Window through the following:

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>close(): void</td>
<td>Closes the Window of the application plug-in instance.</td>
</tr>
<tr>
<td>maximize(): void</td>
<td>Maximizes the Window of the application plug-in instance.</td>
</tr>
<tr>
<td>minimize(): void</td>
<td>Minimizes the Window of the application plug-in instance.</td>
</tr>
<tr>
<td>restore(): void</td>
<td>Restores the Window of the application plug-in instance from a minimized state.</td>
</tr>
<tr>
<td>setTitle(title: string): void</td>
<td>Sets the title of the Window.</td>
</tr>
<tr>
<td>setPosition(pos: {top: number, left: number, width: number, height: number}): void</td>
<td>Sets the position of the Window on the page and the size of the window.</td>
</tr>
<tr>
<td>spawnContextMenu(xPos: number, yPos: number, items: ContextMenuItem[]): void</td>
<td>Opens a context menu on the application plug-in instance, which uses the Context Menu framework.</td>
</tr>
<tr>
<td>registerCloseHandler(handler: () =&gt; Promise&lt;void&gt;): void</td>
<td>Registers a handler, which is called when the Window and application plug-in instance are closed.</td>
</tr>
</tbody>
</table>

### Configuration Dataservice

The Configuration Dataservice is an essential component of the Zowe™ Application Framework, which acts as a JSON resource storage service, and is accessible externally by REST API and internally to the server by dataservices.

The Configuration Dataservice allows for saving preferences of applications, management of defaults and privileges within a Zowe ecosystem, and bootstrapping configuration of the server's dataservices.

The fundamental element of extensibility of the Zowe Application Framework is a plug-in. The Configuration Dataservice works with data for plug-ins. Every resource that is stored in the Configuration Service is stored for a particular plug-in, and valid resources to be accessed are determined by the definition of each plug-in in how it uses the Configuration Dataservice.

The behavior of the Configuration Dataservice is dependent upon the Resource structure for a plug-in. Each plug-in lists the valid resources, and the administrators can set permissions for the users who can view or modify these resources.
**Resource Scope**

Data is stored within the Configuration Dataservice according to the selected *Scope*. The intent of *Scope* within the Dataservice is to facilitate company-wide administration and privilege management of Zowe data.

When a user requests a resource, the resource that is retrieved is an override or an aggregation of the broader scopes that encompass the *Scope* from which they are viewing the data.

When a user stores a resource, the resource is stored within a *Scope* but only if the user has access privilege to update within that *Scope*.

*Scope* is one of the following:

**Product**

Configuration defaults that come with the product. Cannot be modified.

**Site**

Data that can be used between multiple instances of the Zowe Application Server.

**Instance**

Data within an individual Zowe Application Server.

**Group**

Data that is shared between multiple users in a group.(Pending)

**User**

Data for an individual user.(Pending)

*Note:* While Authorization tuning can allow for settings such as GET from Instance to work without login, *User* and *Group* scope queries will be rejected if not logged in due to the requirement to pull resources from a specific user. Because of this, *User* and *Group* scopes will not be functional until the Security Framework is merged into the mainline.

Where *Product* is the broadest scope and *User* is the narrowest scope.

When you specify *Scope User*, the service manages configuration for your particular username, using the authentication of the session. This way, the *User* scope is always mapped to your current username.

Consider a case where a user wants to access preferences for their text editor. One way they could do this is to use the REST API to retrieve the settings resource from the *Instance* scope.

The *Instance* scope might contain editor defaults set by the administrator. But, if there are no defaults in *Instance*, then the data in *Group* and *User* would be checked.

Therefore, the data the user receives would be no broader than what is stored in the *Instance* scope, but might have only been the settings they saved within their own *User* scope (if the broader scopes do not have data for the resource).

Later, the user might want to save changes, and they try to save them in the *Instance* scope. Most likely, this action will be rejected because of the preferences set by the administrator to disallow changes to the *Instance* scope by ordinary users.

**REST API**

When you reach the Configuration Service through a REST API, HTTP methods are used to perform the desired operation.

The HTTP URL scheme for the configuration dataservice is:

```
<Server>/plugins/com.rs.configjs/services/data/<plugin ID>/<Scope>/<resource>/<optional subresources>?<query>
```

Where the resources are one or more levels deep, using as many layers of subresources as needed.
Think of a resource as a collection of elements, or a directory. To access a single element, you must use the query parameter "name="

**REST query parameters**

**Name** (string)

Get or put a single element rather than a collection.

**Recursive** (boolean)

When performing a DELETE, specifies whether to delete subresources too.

**Listing** (boolean)

When performing a GET against a resource with content subresources, listing=true will provide the names of the subresources rather than both the names and contents.

**REST HTTP methods**

Below is an explanation of each type of REST call.

Each API call includes an example request and response against a hypothetical application called the "code editor".

**GET**

GET /plugins/com.rs.configjs/services/data/<plugin>/<scope>/<resource>?
name=<element>

• This returns JSON with the attribute "content" being a JSON resource that is the entire configuration that was requested. For example:

/plugins/com.rs.configjs/services/data/org.openmainframe.zowe.codeeditor/user
sessions/default?name=tabs

The parts of the URL are:

• Plugin: org.openmainframe.zowe.codeeditor
• Scope: user
• Resource: sessions
• Subresource: default
• Element = tabs

The response body is a JSON config:

```json
{
  "_objectType": "com.rs.config.resource",
  "_metadataVersion": "1.1",
  "resource": "org.openmainframe.zowe.codeeditor/USER/sessions/default",
  "contents": {
    "_metadataVersion": "1.1",
    "_objectType": "org.openmainframe.zowe.codeeditor.sessions.tabs",
    "tabs": [{
      "title": "TSSPG.REXX.EXEC(ARCTEST2)",
      "filePath": "TSSPG.REXX.EXEC(ARCTEST2)",
      "isDataset": true
    }, {
      "title": ".profile",
      "filePath": "/u/tsspg/.profile"
    }]
  }
}
```

GET /plugins/com.rs.configjs/services/data/<plugin>/<scope>/<resource>
This returns JSON with the attribute `content` being a JSON object that has each attribute being another JSON object, which is a single configuration element.

GET /plugins/com.rs.configjs/services/data/<plugin>/<scope>/<resource>

(When subresources exist.)

This returns a listing of subresources that can, in turn, be queried.

**PUT**

PUT /plugins/com.rs.configjs/services/data/<plugin>/<scope>/<resource>?name=<element>

Stores a single element (must be a JSON object {...}) within the requested scope, ignoring aggregation policies, depending on the user privilege. For example:

/Plugins/com.rs.configjs/services/data/org.openmainframe.zowe.codeeditor/user/sessions/default?name=tabs

Body:

```json
{
   "_metadataVersion" : "1.1",
   "_objectType" : "org.openmainframe.zowe.codeeditor.sessions.tabs",
   "tabs" : [
      {
         "title" : ".profile",
         "filePath" : "/u/tsspg/.profile"
      },
      {
         "title" : "TSSPG.REXX.EXEC(ARCTEST2)",
         "filePath" : "TSSPG.REXX.EXEC(ARCTEST2)",
         "isDataset" : true
      },
      {
         "title" : ".emacs",
         "filePath" : "/u/tsspg/.emacs"
      }
   ]
}
```

Response:

```json
{
   "_objectType" : "com.rs.config.resourceUpdate",
   "_metadataVersion" : "1.1",
   "resource" : "org.openmainframe.zowe.codeeditor/USER/sessions/default",
   "result" : "Replaced item."
}
```

**DELETE**

DELETE /plugins/com.rs.configjs/services/data/<plugin>/<scope>/<resource>?recursive=true

Deletes all files in all leaf resources below the resource specified.

DELETE /plugins/com.rs.configjs/services/data/<plugin>/<scope>/<resource>?name=<element>

Deletes a single file in a leaf resource.

DELETE /plugins/com.rs.configjs/services/data/<plugin>/<scope>/<resource>

- Deletes all files in a leaf resource.
- Does not delete the directory on disk.
Administrative access and group

By means not discussed here, but instead handled by the server's authentication and authorization code, a user might be privileged to access or modify items that they do not own.

In the simplest case, it might mean that the user is able to do a PUT, POST, or DELETE to a level above User, such as Instance.

The more interesting case is in accessing another user's contents. In this case, the shape of the URL is different. Compare the following two commands:

GET /plugins/com.rs.configjs/services/data/<plugin>/user/<resource>

Gets the content for the current user.

GET /plugins/com.rs.configjs/services/data/<plugin>/users/<username>/<resource>

Gets the content for a specific user if authorized.

This is the same structure that is used for the Group scope. When requesting content from the Group scope, the user is checked to see if they are authorized to make the request for the specific group. For example:

GET /plugins/com.rs.configjs/services/data/<plugin>/group/<groupname>/
<resource>

Gets the content for the given group, if the user is authorized.

Application API

Retrieves and stores configuration information from specific scopes.

Note: This API should only be used for configuration administration user interfaces.

ZLUX.UriBroker.pluginConfigForScopeUri(pluginDefinition: ZLUX.Plugin, scope: string, resourcePath:string, resourceName:string): string;

A shortcut for the preceding method, and the preferred method when you are retrieving configuration information, is simply to "consume" it. It "asks" for configurations using the User scope, and allows the configuration service to decide which configuration information to retrieve and how to aggregate it. (See below on how the configuration service evaluates what to return for this type of request).

ZLUX.UriBroker.pluginConfigUri(pluginDefinition: ZLUX.Plugin, resourcePath:string, resourceName:string): string;

Internal and bootstrapping

Some dataservices within plug-ins can take configuration that affects their behavior. This configuration is stored within the Configuration Dataservice structure, but it is not accessible through the REST API.

Within the instance configuration directory of a zLUX installation, each plugin may optionally have an _internal directory. An example of such a path would be:

~/.zowe/workspace/app-server/ZLUX/pluginStorage/<pluginName>/_internal

Within each _internal directory, the following directories might exist:

- services/<servicename>: Configuration resources for the specific service.
- plugin: Configuration resources that are visible to all services in the plug-in.

The JSON contents within these directories are provided as Objects to dataservices through the dataservice context Object.

Plug-in definition

Because the Configuration Dataservices stores data on a per-plug-in basis, each plug-in must define their resource structure to make use of the Configuration Dataservice. The resource structure definition is included in the plug-in's pluginDefinition.json file.
For each resource and subresource, you can define an aggregationPolicy to control how the data of a broader scope alters the resource data that is returned to a user when requesting a resource from a narrower Scope.

For example:

```json
"configurationData": { //is a direct attribute of the pluginDefinition
  "resources": { //always required
    "preferences": {
      "locationType": "relative", //this is the only option for now, but later absolute paths may be accepted
      "aggregationPolicy": "override" //override and none for now, but more in the future
    },
    "sessions": { //the name at this level represents the name used within a URL, such as /plugins/com.rs.configjs/services/data/org.openmainframe.zowe.codeeditor/user/sessions
      "aggregationPolicy": "none",
      "subResources": {
        "sessionName": {
          "variable": true, //if variable=true is present, the resource must be the only one in that group but the name of the resource is substituted for the name given in the REST request, so it represents more than one
          "aggregationPolicy": "none"
        }
      }
    }
  }
}
```

### Aggregation policies

Aggregation policies determine how the Configuration Dataservice aggregates JSON objects from different Scopes together when a user requests a resource. If the user requests a resource from the User scope, the data from the User scope might replace or be merged with the data from a broader scope such as Instance, to make a combined resource object that is returned to the user.

Aggregation policies are defined by a plug-in developer in the plug-in's definition for the Configuration Service, as the attribute aggregationPolicy within a resource.

The following policies are currently implemented:

- **NONE**: If the Configuration Dataservice is called for Scope User, only user-saved settings are sent, unless there are no user-saved settings for the query, in which case the dataservice attempts to send data that is found at a broader scope.
- **OVERRIDE**: The Configuration Dataservice obtains data for the resource that is requested at the broadest level found, and joins the resource's properties from narrower scopes, overriding broader attributes with narrower ones, when found.

### URI Broker

The URI Broker is an object in the application plug-in web framework, which facilitates calls to the Zowe™ Application Server by constructing URIs that use the context from the calling application plug-in.

#### Accessing the URI Broker

The URI Broker is accessible independent of other frameworks involved such as Angular, and is also accessible through iframe. This is because it is attached to a global when within the Zowe Desktop. For more information, see Zowe Desktop and window management on page 263. Access the URI Broker through one of two locations:

Natively:
window.ZoweZLUX.uriBroker

In an iframe:
window.parent.ZoweZLUX.uriBroker

Functions
The URI Broker builds the following categories of URIs depending upon what the application plug-in is designed to call.

Accessing an application plug-in's dataservices
Dataservices can be based on HTTP (REST) or Websocket. For more information, see Dataservices on page 251.

HTTP Dataservice URI

pluginRESTUri(plugin: ZLUX.Plugin, serviceName: string, relativePath: string): string

Returns: A URI for making an HTTP service request.

Websocket Dataservice URI

pluginWSUri(plugin: ZLUX.Plugin, serviceName: string, relativePath: string): string

Returns: A URI for making a Websocket connection to the service.

Accessing application plug-in's configuration resources
Defaults and user storage might exist for an application plug-in such that they can be retrieved through the Configuration Dataservice.

There are different scopes and actions to take with this service, and therefore there are a few URIs that can be built:

Standard configuration access

pluginConfigUri(pluginDefinition: ZLUX.Plugin, resourcePath: string, resourceName?: string): string

Returns: A URI for accessing the requested resource under the user's storage.

Scoped configuration access

pluginConfigForScopeUri(pluginDefinition: ZLUX.Plugin, scope: string, resourcePath: string, resourceName?: string): string

Returns: A URI for accessing a specific scope for a given resource.

Accessing static content
Content under an application plug-in's web directory is static content accessible by a browser. This can be accessed through:

pluginResourceUri(pluginDefinition: ZLUX.Plugin, relativePath: string): string

Returns: A URI for getting static content.

For more information about the web directory, see Application plug-in filesystem structure on page 243.

Accessing the application plug-in's root
Static content and services are accessed off of the root URI of an application plug-in. If there are other points that you must access on that application plug-in, you can get the root:

pluginRootUri(pluginDefinition: ZLUX.Plugin): string

Returns: A URI to the root of the application plug-in.
Server queries

A client can find different information about a server’s configuration or the configuration as seen by the current user by accessing specific APIs.

Accessing a list of plug-ins

`pluginListUri(pluginType: ZLUX.PluginType): string`

Returns: A URI, which when accessed returns the list of existing plug-ins on the server by type, such as "Application" or "all".

Application-to-application communication

Zowe™ application plug-ins can opt-in to various application framework abilities, such as the ability to have a Logger, use of a URI builder utility, and more. One ability that is unique to a Zowe environment with multiple application plug-ins is the ability for one application plug-in to communicate with another. The application framework provides constructs that facilitate this ability. The constructs are: the Dispatcher, Actions, Recognizers, Registry, and the features that utilize them such as the framework's Context menu.

1. Why use application-to-application communication? on page 273
2. Actions on page 273
3. Recognizers on page 275
4. Dispatcher on page 277

Why use application-to-application communication?

When working with a computer, people often use multiple applications to accomplish a task, for example checking a dashboard before using a detailed program or checking email before opening a bank statement in a browser. In many environments, the relationship between one program and another is not well defined (you might open one program to learn of a situation, which you solve by opening another program and typing or pasting in content). Or perhaps a hyperlink is provided or an attachment, which opens a program using a lookup table of which the program is the default for handling a certain file extension. The application framework attempts to solve this problem by creating structured messages that can be sent from one application plug-in to another. An application plug-in has a context of the information that it contains. You can use this context to invoke an action on another application plug-in that is better suited to handle some of the information discovered in the first application plug-in. Well-structured messages facilitate knowing what application plug-in is "right" to handle a situation, and explain in detail what that application plug-in should do. This way, rather than finding out that the attachment with the extension ".dat" was not meant for a text editor, but instead for an email client, one application plug-in might instead be able to invoke an action on an application plug-in, which can handle opening of an email for the purpose of forwarding to others (a more specific task than can be explained with filename extensions).

Actions

To manage communication from one application plug-in to another, a specific structure is needed. In the application framework, the unit of application-to-application communication is an Action. The typescript definition of an Action is as follows:

```typescript
export class Action implements ZLUX.Action {
  id: string;           // id of action itself.
  i18nNameKey: string;  // future proofing for I18N
  defaultName: string;  // default name for display purposes, w/o I18N
  description: string;
  targetMode: ActionTargetMode;
  type: ActionType;   // "launch", "message"
  targetPluginID: string;
  primaryArgument: any;

  constructor(id: string,    
              defaultName: string,    
              targetMode: ActionTargetMode,    
              description: string,    
              targetPluginID: string,    
              type: ActionType,    
              primaryArgument: any) {
    this.id = id;
    this.i18nNameKey = i18nNameKey;
    this.defaultName = defaultName;
    this.description = description;
    this.targetMode = targetMode;
    this.type = type;
    this.targetPluginID = targetPluginID;
    this.primaryArgument = primaryArgument;
  }
}
```
An Action has a specific structure of data that is passed, to be filled in with the context at runtime, and a specific target to receive the data. The Action is dispatched to the target in one of several modes, for example: to target a specific instance of an application plug-in, an instance, or to create a new instance. The Action can be less detailed than a message. It can be a request to minimize, maximize, close, launch, and more. Finally, all of this information is related to a unique ID and localization string such that it can be managed by the framework.

**Action target modes**

When you request an Action on an application plug-in, the behavior is dependent on the instance of the application plug-in you are targeting. You can instruct the framework how to target the application plug-in with a target mode from the `ActionTargetMode` enum:

```typescript
export enum ActionTargetMode {
  PluginCreate,                // require pluginType
  PluginFindUniqueOrCreate,    // required AppInstance/ID
  PluginFindAnyOrCreate,       // plugin type
  //TODO PluginFindAnyOrFail
  System,                      // something that is always present
}
```

**Action types**

The application framework performs different operations on application plug-ins depending on the type of an Action. The behavior can be quite different, from simple messaging to requesting that an application plug-in be minimized. The types are defined by an enum:

```typescript
export enum ActionType {       // not all actions are meaningful for all
target modes
  Launch,                      // essentially do nothing after target mode
  Focus,                       // bring to fore, but nothing else
  Route,                       // sub-navigate or "route" in target
  Message,                     // "onMessage" style event to plugin
  Method,                      // Method call on instance, more strongly
  Minimize,                    // may need to call a "close handler"
  Maximize,
  Close,
}
```

**Loading actions**

Actions can be created dynamically at runtime, or saved and loaded by the system at login.
Dynamically
You can create Actions by calling the following Dispatcher method: `makeAction(id: string, defaultName: string, targetMode: ActionTargetMode, type: ActionType, targetPluginID: string, primaryArgument: any): Action`

Saved on system
Actions can be stored in JSON files that are loaded at login. The JSON structure is as follows:

```json
{
   "actions": [
   {
      "id": "org.zowe.explorer.openmember",
      "defaultName": "Edit PDS in MVS Explorer",
      "type": "Launch",
      "targetMode": "PluginCreate",
      "targetId": "org.zowe.explorer",
      "arg": {
         "type": "edit_pds",
         "pds": {
            "op": "deref",
            "source": "event",
            "path": [
               "full_path"
            ]
         }
      }
   }
   ]
}
```

Recognizers
Actions are meant to be invoked when certain conditions are met. For example, you do not need to open a messaging window if you have no one to message. Recognizers are objects within the application framework that use the context that the application plug-in provides to determine if there is a condition for which it makes sense to execute an Action. Each recognizer has statements about what condition to recognize, and upon that statement being met, which Action can be executed at that time. The invocation of the Action is not handled by the Recognizer; it simply detects that an Action can be taken.

Recognition clauses
Recognizers associate a clause of recognition with an action, as you can see from the following class:

```typescript
export class RecognitionRule {
   predicate: RecognitionClause;
   actionID: string;

   constructor(predicate: RecognitionClause, actionID: string) {
      this.predicate = predicate;
      this.actionID = actionID;
   }
}
```

A clause, in turn, is associated with an operation, and the subclauses upon which the operation acts. The following operations are supported:

```typescript
export enum RecognitionOp {
   AND, OR, NOT, PROPERTY_EQ,
}
```
SOURCE_PLUGIN_TYPE, // syntactic sugar
MIME_TYPE,     // ditto
}

**Loading Recognizers at runtime**

You can add a Recognizer to the application plug-in environment in one of two ways: by loading from Recognizers saved on the system, or by adding them dynamically.

**Dynamically**

You can call the Dispatcher method,`addRecognizer(predicate:RecognitionClause, actionID:string):void`

**Saved on system**

Recognizers can be stored in JSON files that are loaded at login. The JSON structure is as follows:

```json
{
  "recognizers": [
    {
      "id":"<actionID>",
      "clause": {
        <clause>
      }
    }
  ]
}
```

*clause* can take on one of two shapes:

"prop": ["<keyString>", "<valueString>"]

Or,

"op": "<op enum as string>",
"args": [ {
  <clause>
}
]

Where this one can again, have subclauses.

**Recognizer example**

Recognizers can be as simple or complex as you write them to be, but here is an example to illustrate the mechanism:

```json
{
  "recognizers": [
    {
      "id":"org.zowe.explorer.openmember",
      "clause": {
        "op": "AND",
        "args": [
          {
            "prop": ["sourcePluginID","org.zowe.terminal.tn3270"],
            "prop": ["screenID","ISRUDSM"]
          }
        ]
      }
    }
  ]
}
```
In this case, the Recognizer detects whether it is possible to run the `org.zowe.explorer.openmember` Action when the TN3270 Terminal application plug-in is on the screen ISRUDSM (an ISPF panel for browsing PDS members).

**Dispatcher**

The dispatcher is a core component of the application framework that is accessible through the Global ZLUX Object at runtime. The Dispatcher interprets Recognizers and Actions that are added to it at runtime. You can register Actions and Recognizers on it, and later, invoke an Action through it. The dispatcher handles how the Action's effects should be carried out, acting in combination with the Window Manager and application plug-ins to provide a channel of communication.

**Registry**

The Registry is a core component of the application framework, which is accessible through the Global ZLUX Object at runtime. It contains information about which application plug-ins are present in the environment, and the abilities of each application plug-in. This is important to application-to-application communication, because a target might not be a specific application plug-in, but rather an application plug-in of a specific category, or with a specific featureset, capable of responding to the type of Action requested.

**Pulling it all together in an example**

The standard way to make use of application-to-application communication is by having Actions and Recognizers that are saved on the system. Actions and Recognizers are loaded at login, and then later, through a form of automation or by a user action, Recognizers can be polled to determine if there is an Action that can be executed. All of this is handled by the Dispatcher, but the description of the behavior lies in the Action and Recognizer that are used. In the Action and Recognizer descriptions above, there are two JSON definitions: One is a Recognizer that recognizes when the Terminal application plug-in is in a certain state, and another is an Action that instructs the MVS Explorer to load a PDS member for editing. When you put the two together, a practical application is that you can launch the MVS Explorer to edit a PDS member that you have selected within the Terminal application plug-in.

**Configuring IFrame communication**

The Zowe Application Framework provides the following shared resource functions through a ZoweZLUX object: `pluginManager`, `uriBroker`, `dispatcher`, `logger`, `registry`, `notificationManager`, and `globalization`.

Like REACT and Angular apps, IFrame apps can use the ZoweZLUX object to communicate with the framework and other apps. To enable communication in an IFrame app, you must add the following javascript to your app, for example in your `index.html` file:

```html
<script>
if (exports) {
    var ZoweZLUX_tempExports = exports;
}
var exports = {"__esModule": true};
</script>
<script type="text/javascript" src="/lib/org.zowe.zlux.logger/0.9.0/logger.js"></script>
<script type="text/javascript" src="/org.zowe.zlux.bootstrap/web/iframe-adapter.js"></script>
```

`logger.js` is the javascript version of `logger.ts` and is capable of the same functions, including access to the `Logger` and `ComponentLogger` classes. The `Logger` class determines the behavior of all the `ComponentLoggers` created from it. `ComponentLoggers` are what the user implements to perform logging.

`Iframe-adapter.js` is designed to mimic the ZoweZLUX object that is available to apps within the virtual-desktop, and serves as the middle-man for communication between IFrame apps and the Zowe desktop.

You can see an implementation of this functionality in the sample IFrame app.
The version of ZoweZLUX adapted for IFrame apps is not complete and only implements the functions needed to allow the Sample IFrame App to function. The notificationManager, logger, globalization, dispatcher, windowActions, windowEvents, and viewportEvents are fully implemented. The pluginManager and uriBroker are only partially implemented. The registry is not implemented.

Unlike REACT and Angular apps, in IFrame apps the ZoweZLUX and initialization objects communicate with Zowe using the browser's onmessage and postmessage APIs. That means that communication operations are asynchronous, and you must account for this in your app, for example by using Promise objects and await or then functions.

Error reporting UI

The zLUX Widgets repository contains shared widget-like components of the Zowe™ Desktop, including Button, Checkbox, Paginator, various pop-ups, and others. To maintain consistency in desktop styling across all applications, use, reuse, and customize existing widgets to suit the purpose of the application's function and look.

Ideally, a program should have little to no logic errors. Once in a while a few occur, but more commonly an error occurs from misconfigured user settings. A user might request an action or command that requires certain prerequisites, for example: a proper ZSS-Server configuration. If the program or method fails, the program should notify the user through the UI about the error and how to fix it. For the purposes of this discussion, we will use the Workflow application plug-in in the zlux-workflow repository.

ZluxPopupManagerService

The ZluxPopupManagerService is a standard popup widget that can, through its reportError() method, be used to display errors with attributes that specify the title or error code, severity, text, whether it should block the user from proceeding, whether it should output to the logger, and other options you want to add to the error dialog. ZluxPopupManagerService uses both ZluxErrorSeverity and ErrorReportStruct.

```
`export declare class ZluxPopupManagerService {

  eventsSubject: any;
  listeners: any;
  events: any;
  logger: any;
  constructor();
  setLogger(logger: any): void;
  on(name: any, listener: any): void;
  broadcast(name: any, ...args: any[]): void;
  processButtons(buttons: any[]): any[];
  block(): void;
  unblock(): void;
  getLoggerSeverity(severity: ZluxErrorSeverity): any;
  reportError(severity: ZluxErrorSeverity, title: string, text: string,
             options?: any): Rx.Observable<any>;
```
```

ZluxErrorSeverity

ZluxErrorSeverity classifies the type of report. Under the popup-manager, there are the following types: error, warning, and information. Each type has its own visual style. To accurately indicate the type of issue to the user, the error or pop-up should be classified accordingly.

```
`export declare enum ZluxErrorSeverity {

  ERROR = "error",
  WARNING = "warning",
  INFO = "info",
```
```
```
**ErrorReportStruct**

ErrorReportStruct contains the main interface that brings the specified parameters of `reportError()` together.

```
`export interface ErrorReportStruct {`
    severity: string;
    modal: boolean;
    text: string;
    title: string;
    buttons: string[];
`}`
```

**Implementation**

Import `ZluxPopupManagerService` and `ZluxErrorSeverity` from widgets. If you are using additional services with your error prompt, import those too (for example, `LoggerService` to print to the logger or `GlobalVeilService` to create a visible semi-transparent gray veil over the program and pause background tasks). Here, widgets is imported from `node_modules\@zlux\` so you must ensure zLUX widgets is used in your `package-lock.json` or `package.json` and you have run `npm install`.

```js
import { ZluxPopupManagerService, ZluxErrorSeverity } from '@zlux/widgets';
```

**Declaration**

Create a member variable within the constructor of the class you want to use it for. For example, in the Workflow application plug-in under `\zlux-workflow\src\app\app\zosmf-server-config.component.ts` is a `ZosmfServerConfigComponent` class with the pop-up manager service variable. To automatically report the error to the console, you must set a logger.

```
`export class ZosmfServerConfigComponent {`
    constructor(
        private popupManager: ZluxPopupManagerService,
    ) {
        popupManager.setLogger(logger); } //Optional
`}`
```

**Usage**

Now that you have declared your variable within the scope of your program's class, you are ready to use the method. The following example describes an instance of the `reload()` method in Workflow that catches an error when the program attempts to retrieve a configuration from a `configService` and set it to the program's `this.config`. This method fails when the user has a faulty zss-Server configuration and the error is caught and then sent to the class' `popupManager` variable from the constructor above.

```
`reload(): void {`
    this.globalVeilService.showVeil();
    this.configService
        .getConfig()
        .then(config => (this.config = config))
        .then(_ => setTimeout(() => this.test(), 0))
        .then(_ => this.globalVeilService.hideVeil())
        .catch(err => {
            this.globalVeilService.hideVeil()
            let errorTitle: string = "Error";
            let errorMessage: string = "Server configuration not found. Please check your zss server."
            const options = {
                blocking: true
            };`
Here, the `errorMessage` clearly describes the error with a small degree of ambiguity as to account for all types of errors that might occur from that method. The specifics of the error are then generated dynamically and are printed with the `err.toString()`, which contains the more specific information that is used to pinpoint the problem. The `this.popupManager.report()` method triggers the error prompt to display. The error severity is set with `ZluxErrorSeverity.ERROR` and the `err.status.toString()` describes the status of the error (often classified by a code, for example: 404). The optional parameters in `options` specify that this error will block the user from interacting with the application plug-in until the error is closed or it until goes away on its own. `globalVeilService` is optional and is used to create a gray veil on the outside of the program when the error is caused. You must import `globalVeilService` separately (see the `zlux-workflow` repository for more information).

**HTML**

The final step is to have the recently created error dialog display in the application plug-in. If you do not add the component to your template, the error will not be displayed. Navigate to your component's `.html` file. On the Workflow application plug-in, this file will be in `\zlux-workflow\src\app\app\zosmf-server-config.component.html` and the only item left is to add the popup manager component alongside your other classes.

```html
<zlux-popup-manager></zlux-popup-manager>
```

So now when the error is called, the new UI element should resemble the following:

![Error Dialog](attachment:ErrorDialog.png)

The order in which you place the pop-up manager determines how the error dialog will overlap in your UI. If you want the error dialog to overlap other UI elements, place it at the end of the `.html` file. You can also create custom styling through a CSS template, and add it within the scope of your application plug-in.

**Logging utility**

The `zlux-shared` repository provides a logging utility for use by dataservices and web content for an application plug-in.

**Logging objects**

The logging utility is based on the following objects:

- **Component Loggers**: Objects that log messages for an individual component of the environment, such as a REST API for an application plug-in or to log user access.
- **Destinations**: Objects that are called when a component logger requests a message to be logged. Destinations determine how something is logged, for example, to a file or to a console, and what formatting is applied.
• **Logger**: Central logging object, which can spawn component loggers and attach destinations.

**Logger IDs**

Because Zowe™ application plug-ins have unique identifiers, both dataservices and an application plug-in's web content are provided with a component logger that knows this unique ID such that messages that are logged can be prefixed with the ID. With the association of logging to IDs, you can control verbosity of logs by setting log verbosity by ID.

**Accessing logger objects**

**Logger**

The core logger object is attached as a global for low-level access.

**App Server**

NodeJS uses `global` as its global object, so the logger is attached to: `global.COM_RS_COMMON_LOGGER`

**Web**

Browsers use `window` as the global object, so the logger is attached to: `window.COM_RS_COMMON_LOGGER`

**Component logger**

Component loggers are created from the core logger object, but when working with an application plug-in, allow the application plug-in framework to create these loggers for you. An application plug-in's component logger is presented to dataservices or web content as follows.

**App Server**

See [Router Dataservice Context](#) in the topic [Dataservices](#) on page 251.

**Web**

(Angular App Instance Injectable). See [Logger](#) in [Zowe Desktop and window management](#) on page 263.

**Using log message IDs**

To make technical support for your application easier, create IDs for common log messages and use substitution to generate them. When you use IDs, people fielding support calls can identify and solve problems more quickly. IDs are particularly helpful if your application is translated, because it avoids users having to explain problems using language that the tech support person might not understand.

To use log message IDs, take the following steps:

1. Depending on how your application is structured, create message files in the following locations:
   - Web log messages: `\src\assets\i18n\log\messages_{language}.json`
   - App server log messages: `\lib\assets\i18n\log\messages_{language}.json`

2. In the files, create ID-message pairs using the following format:

   ```json
   { "id1": "value1", "id2": "value2" [...] }
   ```

   Where "id#" is the message ID and "value#" is the text. For example:

   ```json
   { "A001": "Application created.", "A002": "Application deleted." [...] }
   ```
3. Reference the IDs in your code, for example:

```java
this.log.info("A0001")
```

Which compiles to:

```plaintext
```

Or in another supported language, such as Russian:

```plaintext
DATE TIME:TIME:TIME:TIME <ZWED:> username INFO (org.zowe.app.name,:) A0001 - ########## #######.
```

### Logger API

The following constants and functions are available on the central logging object.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Description</th>
<th>Arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td>makeComponentLogger</td>
<td>function</td>
<td>Returns an existing logger of this name, or creates a new component logger if no logger of the specified name exists - Automatically done by the application framework for dataservices and web content</td>
<td>componentIDString</td>
</tr>
<tr>
<td>setLogLevelForComponentName</td>
<td>function</td>
<td>Sets the verbosity of an existing component logger</td>
<td>componentIDString, logLevel</td>
</tr>
</tbody>
</table>

### Component Logger API

The following constants and functions are available to each component logger.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Description</th>
<th>Arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEVERE</td>
<td>const</td>
<td>Is a const for logLevel</td>
<td>logLevel</td>
</tr>
<tr>
<td>WARNING</td>
<td>const</td>
<td>Is a const for logLevel</td>
<td>logLevel</td>
</tr>
<tr>
<td>INFO</td>
<td>const</td>
<td>Is a const for logLevel</td>
<td>logLevel</td>
</tr>
<tr>
<td>FINE</td>
<td>const</td>
<td>Is a const for logLevel</td>
<td>logLevel</td>
</tr>
<tr>
<td>FINER</td>
<td>const</td>
<td>Is a const for logLevel</td>
<td>logLevel</td>
</tr>
<tr>
<td>FINEST</td>
<td>const</td>
<td>Is a const for logLevel</td>
<td>logLevel</td>
</tr>
<tr>
<td>log</td>
<td>function</td>
<td>Used to write a log, specifying the log level</td>
<td>logLevel, messageString</td>
</tr>
<tr>
<td>severe</td>
<td>function</td>
<td>Used to write a SEVERE log.</td>
<td>messageString</td>
</tr>
<tr>
<td>warn</td>
<td>function</td>
<td>Used to write a WARNING log.</td>
<td>messageString</td>
</tr>
<tr>
<td>info</td>
<td>function</td>
<td>Used to write an INFO log.</td>
<td>messageString</td>
</tr>
<tr>
<td>debug</td>
<td>function</td>
<td>Used to write a FINE log.</td>
<td>messageString</td>
</tr>
</tbody>
</table>
### Attribute

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Description</th>
<th>Arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td>makeSublogger</td>
<td>function</td>
<td>Creates a new component logger with an ID appended by the string given</td>
<td>componentNameSuffix</td>
</tr>
</tbody>
</table>

### Log Levels

An enum, LogLevel, exists for specifying the verbosity level of a logger. The mapping is:

<table>
<thead>
<tr>
<th>Level</th>
<th>Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEVERE</td>
<td>0</td>
</tr>
<tr>
<td>WARNING</td>
<td>1</td>
</tr>
<tr>
<td>INFO</td>
<td>2</td>
</tr>
<tr>
<td>FINE</td>
<td>3</td>
</tr>
<tr>
<td>FINEER</td>
<td>4</td>
</tr>
<tr>
<td>FINEST</td>
<td>5</td>
</tr>
</tbody>
</table>

### Note: The default log level for a logger is INFO.

### Logging verbosity

Using the component logger API, loggers can dictate at which level of verbosity a log message should be visible. You can configure the server or client to show more or less verbose messages by using the core logger's API objects.

Example: You want to set the verbosity of the org.zowe.foo application plug-in's dataservice, bar to show debugging information.

```
logger.setLogLevelForComponentName('org.zowe.foo.bar',LogLevel.DEBUG)
```

### Configuring logging verbosity

The application plug-in framework provides ways to specify what component loggers you would like to set default verbosity for, such that you can easily turn logging on or off.

**Server startup logging configuration**

The server configuration file allows for specification of default log levels, as a top-level attribute logLevel, which takes key-value pairs where the key is a regex pattern for component IDs, and the value is an integer for the log levels.

For example:

```
"logLevel": {
    "com.rs.configjs.data.access": 2,
    // the string given is a regex pattern string, so .* at the end here will cover that service and its subloggers.
    "com.rs.myplugin.myservice.*": 4
    // _' char reserved, and '_' at beginning reserved for server. Just as we reserve
    // '_internal' for plugin config data for config service.
    // _unp = universal node proxy core logging
    // _unp.dauth": 2
},
```

For more information about the server configuration file, see [Zowe Application Framework configuration](#) on page 120.
Zowe lifecycle

This topic describes the lifecycle of Zowe core components and how an offering that provides a Zowe extension can set up lifecycle for their component.

The Zowe UNIX System Services (USS) components are run as part of the started task ZWESVSTC. For more information, see Option 1: Starting Zowe from a USS shell on page 112. There are two key USS directories that play different roles when launching Zowe.

- The Zowe runtime directory <RUNTIME_DIR> that contains the executable files is an immutable set of directories and files that are replaced each time a new release is applied. The initial release or an upgrade is installed either with UNIX shell scripts (see Installing Zowe runtime from a convenience build on page 74), or SMP/E where the runtime directory is laid down initially as FMID AZWE001 and then upgraded through rollup PTF builds (see Installing Zowe SMP/E on page 77). The Zowe runtime directory is not altered during operation of Zowe, so no data is written to it and no customization is performed on its contents.

- The Zowe instance directory <INSTANCE_DIR> contains information that is specific to a launch of Zowe. It contains configuration settings that determine how an instance of the Zowe server is started, such as ports that are used or paths to dependent Java and Node.js runtimes. The instance directory also contains log directory where different 'microservices' write trace data for diagnosis, as well as a workspace and shell scripts to start and stop Zowe. More than one Zowe instance directory can be created to allow multiple launches of a Zowe runtime, each one isolated from each other and starting Zowe depending on how the instance directory has been configured. For more information, see Creating and configuring the Zowe instance directory on page 104.

To start Zowe, the script <INSTANCE_DIR>/bin/zowe-start.sh is run from a USS shell. This uses a REXX program to launch the started task ZWESVSTC, passing the instance directory path as a parameter. It is the equivalent of using the TSO command /S ZWESVSTC,INSTANCE='<INSTANCE_DIR>',JOBNAME='<JOBNAME>'.

The ZWESVSTC PROCLIB uses the program that creates a USS process and starts the script <INSTANCE_DIR>/bin/internal/run-zowe.sh. By using BPXATSL to start the USS process, all of the address spaces started under this shell are managed by SDSF. If the zowe-start.sh run run-zowe.sh directly, the USS processes will not run as a started task and will run under the user ID of whoever ran the run-zowe.sh script rather than the Zowe user ID of ZWESVUSR, likely leading to permission errors accessing the contents of the <RUNTIME_DIR> as well as the Zowe certificate. For these reasons, the zowe-start.sh script launches Zowe's USS process beneath the started task ZWESVSTC.

When run-zowe.sh is run in the USS shell that BPXBATSL creates, it executes the file <INSTANCE_DIR>/instance.env. This file sets a number of shell variables, such as ROOT_DIR that points to the directory with the <RUNTIME_DIR>, variables for all of the ports used by the Zowe components, and other configuration data. For more information, see Reviewing the instance.env file.

Zowe components

Zowe consists of a series of 'microservices' or components. Each component is its own USS directory, which contains its executable files. Within each component's USS directory, a bin directory contains scripts that are used for the lifecycle of the component. When Zowe is started, it identifies the components that are configured to launch and then execute the scripts of those components in the cycle of Validate on page 284, Configure on page 285, and Start on page 285. All components are validated, then all are configured, and finally all are started. This technique is used as follows:

- Used for the base Zowe components that are included with the core Zowe runtime.
- Applies to extensions to allow vendor offerings to be able to have the lifecycle of their 'microservices' within the Zowe USS shell and be included as address spaces under the ZWESVSTC started task.

Validate

Each component is asked to validate itself with a call to its /bin/validate.sh script. This script is optional. If present, the validate.sh script performs tasks such as:

- Check that the shell has the correct prerequisites.
• Validate that ports are available.
• Perform other steps to ensure that the component is able to be launched successfully.

During execution of the `validate.sh` script, if an error is detected, then a component should echo a message that contains information to assist a user diagnosing the problem.

There is no provision for a script that detects an error during validation to stop their component that is being launched. This is expected to be included in a future release of Zowe.

**Configure**

Each component is asked to configure itself with a call to its `/bin/configure.sh` script. This script is optional.

An example configuration step is if a component wants to install applications into the Zowe desktop as iframes, or add API endpoints statically into the API Mediation Layer. Because a component's `configure.sh` script is run inside the USS shell that the instance.env has initialized, it will have all of the shell variables for prerequisites set, so the configure step can be used to query these in order to prepare the component ready for launch.

**Start**

Each component is asked to start itself with a call to its `/bin/start.sh` script. This script is mandatory because without it, the component will not be launched.

It is up to each component to start itself based on how it has been written. We recommend that any variables that someone who configure Zowe may need to vary, such as timeout values, port numbers, or similar, are specified as variables in the instance.env file and then referenced as shell variables in the `start.sh` script to be passed into the component runtime.

**Zowe core components**

The Zowe runtime directory delivers its 'microservices' as components that follow the lifecycle of validate, configure, and start. To understand the type of steps that these scripts perform, you can look at the `<RUNTIME_DIR>/components/` directory. For each of the base Zowe components, look at their `/bin` directories and the scripts they contain.

```
<RUNTIME_DIR>/components/
    /api-mediation
    /app-server
    /explorer-jes
    /explorer-mvs
    /files-api
    /jobs-api
```

**Note:**

The scripts of core Zowe components use the helper library `<RUNTIME_DIR>/scripts/utils`. Currently, these are not publicly supported. Future releases of Zowe might provide these as supported system programming interfaces (SPIs) and include their usage in the Zowe documentation.

**Zowe extensions**

If you want to set up a lifecycle for your Zowe extension, you must provide your own directory that contains your Zowe lifecycle scripts `start.sh`, and optionally `validate.sh` and `configure.sh`.

The `instance.env` file in the `<INSTANCE_DIR>` used to launch Zowe contains the variable `EXTENDER_COMPONENTS` whose value is a semi-colon separated list of fully qualified directory paths that contain extender lifecycle scripts.

**Example:**

Vendor MYVENDOR has a product MYAPP that installs into `/usr/lpp/myvendor/myapp`. This product is a Zowe extension so they want it to be started and stopped with Zowe and run as an address space under the ZWESVSTC in the Zowe USS shell.
The script `/usr/lpp/myvendor/myapp/zowe/validate.sh` checks that the environment has been configured correctly and the script `/usr/lpp/myvendor/myapp/zowe/start.sh` starts the vendor application.

The installation documentation for MYAPP instructs the system programmer to update the `instance.env` file and update the `EXTENDER_COMPONENTS` variable to point to the fully qualified path of the directory that contains the Zowe lifecycle scripts.

```
EXTENDER_COMPONENTS='/usr/lpp/myvendor/myapp/zowe'
```

When the Zowe instance is launched by running `<INSTANCE_DIR>/bin/zowe-start.sh`, this will call the `/usr/lpp/myvendor/myapp/zowe/start.sh` script and the started task will create an address space under `ZWESVSTC` for the vendor component. When the Zowe instance is stopped, the address space is terminated.

**Sample extensions**

**Sample Zowe API extension**

The repository [https://github.com/zowe/sample-node-api](https://github.com/zowe/sample-node-api) contains a sample Zowe extension with a node server providing sample APIs for looking at cars in a dealership. For more information, see [sample-node-api](https://github.com/zowe/sample-node-api).

The `configure.sh` script statically registers the API into the API Mediation Layer as well as a tile that includes the Swagger definitions into the API Catalog.

**Sample Zowe Desktop and API Catalog extension**

The repository [https://github.com/zowe/sample-trial-app](https://github.com/zowe/sample-trial-app) contains a sample Zowe extension with a node server providing a web page that gives a user interface to the APIs included with the API sample above.

The `configure.sh` script installs a web page into the Zowe Desktop by using the utility script `<RUNTIME_DIR>/bin/utils/zowe-install-iframe-plugin.sh`. The `configure.sh` script also installs a tile into the API Mediation Layer's API Catalog.

**Zowe Conformance Program**

**Introduction**

Administered by the Open Mainframe Project, the Zowe™ Conformance Program aims to give users the confidence that when they use a product, app, or distribution that leverages Zowe, they can expect a high level of common functionality, interoperability, and user experience.

Conformance provides Independent Software Vendors (ISVs), System Integrators (SIs), and end users greater confidence that their software will behave as expected. Just like Zowe, the Zowe Conformance Program will continue to evolve and is being developed by committers and contributors in the Zowe community.

As vendors, you are invited to submit conformance testing results for review and approval by the Open Mainframe Project. If your company provides software based on Zowe, you are encouraged to get certified today.

**How to participate**

To participate in the Zowe Conformance Program, follow the process on the [Zowe Conformance Program website](https://github.com/zowe/sample-node-api).

You can also find a list of products that have earned Zowe Conformant status.

To learn the criteria of achieving Zowe conformance for an offering, see [Zowe Conformance Criteria](https://github.com/zowe/sample-node-api).
Chapter 4

Troubleshooting

Topics:

• Overview
• Troubleshooting installation and startup of Zowe z/OS components
• Zowe API Mediation Layer
• Zowe Application Framework
• Troubleshooting z/OS Services
• Zowe CLI
Overview

Troubleshooting

To isolate and resolve Zowe™ problems, you can use the troubleshooting and support information.

Known problems and solutions

Some common problems with Zowe are documented, along with their solutions or workarounds. If you have a problem with Zowe installation and components, review the problem-solution topics to determine whether a solution is available to the problem that you are experiencing.

You can also find error messages and codes, must-gathers, and information about how to get community support in these topics.

- Troubleshooting installation and startup of Zowe z/OS components on page 291
- Troubleshooting API ML on page 293
- Troubleshooting Zowe Application Framework on page 316
- Troubleshooting z/OS Services on page 322
- Troubleshooting Zowe CLI on page 324

Collecting data for Zowe problems

Sometimes you cannot solve a problem by troubleshooting the symptoms. In such cases, you must collect diagnostic data. To collect diagnostic data about Zowe, see Capturing diagnostics to assist problem determination on page 289.

Understanding the Zowe release

Knowing which version of Zowe you are running might help you isolate the problem. Also, the Zowe community who helps you will need to know this information. For more information, see Understanding the Zowe release on page 288.

Understanding the Zowe release

Zowe releases

Zowe uses semantic versioning for its releases, also known as SemVer. Each release has a unique ID made up of three numbers that are separated by periods.

Each time a new release is created, the release ID is incremented. Each number represents the content change since the previous release. For example,

- 1.5.0 represents the fifth minor release since the first major release.
- 1.5.1 represents the first patch to the 1.5.0 release.
- 1.6.0 is the first minor release to be created after 1.5.1.

Patch

A patch is usually reserved for a bug fix to a minor release.

Minor release

A minor release indicates that new functionality is added but the code is compatible with an earlier version. The Zowe community works on two-week sprints and creates a minor release at the end of these, typically once per month although the frequency might vary.
Major release

A major release is required if changes are made to the public API and the code is no longer compatible with an earlier version.

When Zowe is version one, it is associated with the Zowe v1 Zowe Conformance Program on page 286. Offerings that extend Zowe and achieve the Zowe v1 conformance badge will remain compatible with Zowe throughout its version 1 lifetime. A major release increment because of incompatibility is sometimes referred to as a "breaking" change.

The first SMP/E build for Zowe v1 has a Functional Module ID (FMID) of AZWE001, which was created with content from the 1.9.0 release. Each major release will be its own SMP/E FMID where the last digit is updated, for example AZWE00V where V represents the major version.

Subsequent minor and patch releases to V1 are delivered as SMP/E PTF SYSMODs. Because of the size of the content, two co-requisite PTFs are created for each Zowe release.

While Major releases are required for a "breaking" change, they also can be used to indicate to the community a significant content update over and above what would be included in a minor release.

Check the Zowe release number

To see the release number of Zowe, look at the manifest.json file. This is included in the top-level Installing Zowe runtime from a convenience build on page 74, the top-level directory of a Zowe runtime <ROOT_DIR>, and the Creating and configuring the Zowe instance directory on page 104 <INSTANCE_DIR>/workspace.

To see the version of a Zowe release, use the Unix grep command in a directory that contains a manifest.json file.

```bash
> cat manifest.json | grep version | head -1
```

will return a single line with the Zowe release number. For example,

```
"version": "1.10.0",
```

Capturing diagnostics to assist problem determination

To help Zowe™ Open Community effectively troubleshoot Zowe, a shell script zowe-support.sh captures diagnostics data that is required for successful problem determination. By running the shell script on your z/OS environment, you receive a set of output files, which contain all relevant diagnostics data necessary to start a troubleshooting process. You can find the zowe-support.sh script in the <INSTANCE_DIRECTORY>/bin directory. To determine the <INSTANCE_DIRECTORY> for a Zowe started task, open the JESJCL step in the ZWESVSTC task and navigate to the line including //STARTING EXEC ZWESVSTC,INSTANCE=. The <INSTANCE_DIRECTORY>/bin/zowe-support.sh script captures the following data:

- Started task output
  - Zowe server started task
  - Zowe Cross Memory started task (STC)
    - Zowe CLI or REXX (TSO output command, STATUS, capture all)

**Note:** You will need to install the TSO exit IKJEFF53 to permit the TSO OUTPUT command to collect the Zowe started task output. If this exit is not enabled, you will see an error message when you run zowe-support.sh:

```
IKJ56328I JOB jobname REJECTED - JOBNAME MUST BE YOUR USERID OR MUST START WITH YOUR USERID
```

For how to correct this error, see the TSO/E installation exit IKJEFF53 topic in IBM Knowledge Center. The above is the authoritative description, and will be the first to reflect changes. To assist you, a summary of the situation and actions you could take to allow TSO OUTPUT to work in your installation are provided in IKJ56328I JOB job name REJECTED on page 290.
- Zowe Install log
- Scripts that are called from run-zowe.sh
- Versions:
  - manifest.json
  - z/OS version
  - Java version
  - Node version
- Additional logs
  - Zowe app server
  - zLUX app server
- Process list with CPU info with the following data points:
  - Running command and all arguments of the command
  - Real time that has elapsed since the process started
  - Job name
  - Process ID as a decimal number
  - Parent process ID as a decimal number
  - Processor time that the process used
  - Process user ID (in a form of user name if possible, or as a decimal user ID if not possible)

**Running the diagnostic support script**

To run the `zowe-support.sh` script, issue the following commands:

```
cd <INSTANCE_DIRECTORY>/bin
./zowe-support.sh
```

**Problems that may occur running the diagnostic script**

**IKJ56328I JOB job name REJECTED**

**Audience:** Zowe users or the personnel who collects support logs. These individuals should also inform their z/OS system programmer.

The `zowe-support.sh` script collects logs that your support team needs to assist you with problem determination. One of the logs it collects is the JES job log for Zowe tasks. The `zowe-support.sh` script uses the TSO OUTPUT command to collect these logs. On an unmodified z/OS system, the TSO OUTPUT command is restricted to jobs starting with your user ID, and the Zowe tasks will typically have a different job name. You will know that the TSO OUTPUT command is restricted if you see the following message when you issue the TSO OUTPUT command for a job whose job name does not start with your user ID.

```
IKJ56328I JOB job name REJECTED - JOB NAME MUST BE YOUR USERID OR MUST START WITH YOUR USERID
```

Job name filtering is controlled by an exit that is called by the TSO OUTPUT command. The exit is named IKJEFF53. IBM provides the source code for a replacement exit that can remove this restriction in SYS1.SAMPLIB(IKJEFF53) which you can tailor and use instead. Review this exit and if it meets your needs, assemble it and replace it in your LINKLIB concatenation.

**Warning:** You are strongly advised to take great care before attempting to modify LINKLIB directly. You could easily corrupt your entire z/OS system and require an IPL or reinstallation of z/OS. Consult your system programmer before you continue. You should also read the TSO/E installation exit IKJEFF53 topic in the IBM Knowledge Center.

The original exit load module has the following attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command</td>
<td>SYS1.LINKLIB</td>
</tr>
<tr>
<td>CSR</td>
<td></td>
</tr>
</tbody>
</table>
The replacement exit load module has the following attributes when assembled and linked:

<table>
<thead>
<tr>
<th>Name</th>
<th>Prompt</th>
<th>Alias-of</th>
<th>Size</th>
<th>TTR</th>
<th>AC</th>
<th>AM</th>
</tr>
</thead>
<tbody>
<tr>
<td>RM</td>
<td>_______</td>
<td>IKJEFF53</td>
<td>000002A0</td>
<td>03A91D</td>
<td>00</td>
<td>24</td>
</tr>
<tr>
<td>24</td>
<td>_______</td>
<td>IKJEFF53</td>
<td>00000380</td>
<td>0CF015</td>
<td>00</td>
<td>24</td>
</tr>
</tbody>
</table>

The replacement exit load module has the following attributes when assembled and linked:

It is safer to add a module to a private dataset further down the LINKLIST concatenation than to modify SYS1.LINKLIB directly. You can display the LINKLIST with this command at the operator console:

```
D PROG, LNKLST
```

The private dataset or the exit itself does not have to be APF-authorized.

Whichever library you choose, rename IKJEFF53 in SYS1.LINKLIB (or its first occurrence in the LINKLIST concatenation) and add the assembled load module IKJEFF53 to your chosen library.

To activate your changes, refresh the link-list lookaside list with this command:

```
F LLA, REFRESH
```

Now your TSO OUTPUT command will work as described in SYS1.SAMPLIB(IKJEFF53).

Note that this change will affect all users of the TSO OUTPUT command on LPARS sharing the SYS1.LINKLIB dataset. It is not limited to Zowe users. Consult your system programmer to ensure that this change does not impact your site rules about the OUTPUT command, because the specified jobs will be PURGED from the JES output queue if this exit is implemented as described above.

## Troubleshooting installation and startup of Zowe z/OS components

The following topics contain information that can help you troubleshoot problems when you encounter unexpected behavior installing Zowe z/OS components or starting Zowe's ZWESVSTC started task.

### Unable to create BPXAS instances

**Symptom:**

When you start ZWESVSTC started task, either by running the `zowe-start.sh` script or by launching the started task directly, you encounter the following error in the log:

```
<ROOT_DIR>/bin/internal/run-zowe.sh 1: FSUM7726 cannot fork: reason code = 094500f7: EDCS112I Resource temporarily unavailable.
```

You will also encounter the following messages in the SYSLOG:

```
0290  S ZWESVSTC
0281  $HASP100 ZWESVSTC ON STCINRDR
0290  IEF695I START ZWESVSTC WITH JOBNAME ZWESVSTC IS ASSIGNED TO USER
```
ZWESVUSR, GROUP ZWEADMIN

0281 $HASP373 ZWESVSTC STARTED

0090 IEA602I ADDRESS SPACE CREATE FAILED. MAXUSERS WOULD HAVE BEEN EXCEEDED

0290 BPXP005I A FORK OR SPAWN ERROR WAS ENCOUNTERED. RETURN CODE 00000070 REASON CODE 094500F7

0090 IEA602I ADDRESS SPACE CREATE FAILED. MAXUSERS WOULD HAVE BEEN EXCEEDED

Solution:
This problem occurs when the maximum number of BPXAS instances have been reached. This may be because when the Zowe instance directory was created, it was generated in the same location as the Zowe root directory. The Zowe instance directory is created by using the script `<ROOT_DIR>/bin/zowe-configure-instance.sh -c <PATH_TO_INSTANCE_DIR>`. See Creating an instance directory on page 105. The Zowe runtime directory is replaced when new PTFs are applied and should be considered as a read-only set of files. Zowe instance directories are designed to live outside the directory structure and are used to start a Zowe runtime. This problem will only occur with Zowe drivers prior to v1.10 and has been resolved in v1.10 where the `zowe-configure-instance.sh` script will report error if it detects the `-c` argument because the installation directory location is an existing Zowe runtime directory.

Errors caused when running the Zowe desktop with node 8.16.1

Symptom:
When you start the ZWESVSTC started task, you encounter the following error messages:

```
/usr/lpp/zowe/components/app-server/share/zlux-app-server/lib/initInstance.js:1
(function (exports, require, module, __filename, __dirname) {
    SyntaxError: Invalid or unexpected token
    at createScript (vm.js:80:10)
    at Object.runInThisContext (vm.js:139:10)
    at Module._compile (module.js:617:28)
    at Object.Module._extensions..js (module.js:664:10)
    at Module.load (module.js:566:32)
    at tryModuleLoad (module.js:506:12)
    at Function.Module._load (module.js:498:3)
    at Function.Module.runMain (module.js:694:10)
    at startup (bootstrap_node.js:204:16)
    at bootstrap_node.js:625:3
```

```
/global/zowe/instances/prod/bin/internal/run-zowe.sh 3: FSUM7332 syntax error: got }, expecting Newline
```

Solution:
This problem occurs when you use Node.js v8.16.1 which is not supported on Zowe. There is a known issue with node.js v8.16.1 and Zowe desktop encoding. Use a supported version of Node.js instead. For more information, see Supported Node.js versions on page 50.
Cannot start Zowe and UNIX commands not found with FSUM7351

**Symptom:**
When you start the ZWESVSTC started task, you might encounter the following error message:

```plaintext
dirname: <instance-dir>/bin/internal/run-zowe.sh 2: FSUM7351 not found
pwd: <instance-dir>/bin/internal/run-zowe.sh 2: FSUM7351 not found
.: <instance-dir>/bin/internal/run-zowe.sh 3: /bin/internal/read-instance.sh: not found
```

**Solution:**
Check that `/bin` is part on your PATH. Do `echo $PATH` to check. If it is missing, make sure that it is appended to PATH in your profile, for example, in `/etc/profile/`.

---

Zowe API Mediation Layer

Troubleshooting API ML

As an API Mediation Layer user, you may encounter problems with how the API ML functions. This article presents known API ML issues and their solutions.

**Enable API ML Debug Mode**

Use debug mode to activate the following functions:

- Display additional debug messages for API ML
- Enable changing log level for individual code components

**Important:** We highly recommend that you enable debug mode only when you want to troubleshoot issues. Disable debug mode when you are not troubleshooting. Running in debug mode while operating API ML can adversely affect its performance and create large log files that consume a large volume of disk space.

**Follow these steps:**

1. Open the file `<Zowe install directory>/components/api-mediation/bin/start.sh`.
2. Find the API Mediation Layer service, for which you want to enable the debug mode: discovery, catalog, or gateway.
3. Find the line that contains the `LOG_LEVEL=` parameter and set the value to `debug`:
   ```plaintext
   LOG_LEVEL=debug
   ```
4. Restart Zowe™.
   You have enabled the debug mode.
5. (Optional) Reproduce a bug that causes issues and review debug messages. If you are unable to resolve the issue, create an issue here.
6. Disable the debug mode. Find the `LOG_LEVEL` parameter, and change its current value to the default `LOG_LEVEL= one`:
   ```plaintext
   LOG_LEVEL=
   ```
7. Restart Zowe.
   You have disabled the debug mode.

**Change the Log Level of Individual Code Components**

You can change the log level of a particular code component of the API ML internal service at run time.

**Follow these steps:**
1. Enable API ML Debug Mode as described in Enable API ML Debug Mode. This activates the application/loggers endpoints in each API ML internal service (Gateway, Discovery Service, and Catalog).

2. List the available loggers of a service by issuing the GET request for the given service URL:

   ```
   GET scheme://hostname:port/application/loggers
   ```

   Where:
   - **scheme**
     API ML service scheme (http or https)
   - **hostname**
     API ML service hostname
   - **port**
     TCP port where API ML service listens on. The port is defined by the configuration parameter MFS_GW_PORT for the Gateway, MFS_DS_PORT for the Discovery Service (by default, set to gateway port + 1), and MFS_AC_PORT for the Catalog (by default, set to gateway port + 2).

   **Exception:** For the catalog you will able to get list the available loggers by issuing the GET request for the given service URL:

   ```
   GET [gateway-scheme]:/[gateway-hostname]:[gateway-port]/api/v1/apicatalog/application/loggers
   ```

   **Tip:** One way to issue REST calls is to use the http command in the free HTTPie tool: https://httpie.org/.

   **Example:**

   ```
   HTTPie command:
   http GET https://lpar.ca.com:10000/application/loggers
   ```

   Output:
   ```
   {"levels": ["OFF", "ERROR", "WARN", "INFO", "DEBUG", "TRACE"],
   "loggers": {
     "ROOT": { "configuredLevel": "INFO", "effectiveLevel": "INFO" },
     "com": { "configuredLevel": null, "effectiveLevel": "INFO" },
     "com.ca": { "configuredLevel": null, "effectiveLevel": "INFO" },
     ...
   }
   ```

3. Alternatively, you extract the configuration of a specific logger using the extended GET request:

   ```
   GET scheme://hostname:port/application/loggers/{name}
   ```

   Where:
   - **{name}**
     is the logger name

4. Change the log level of the given component of the API ML internal service. Use the POST request for the given service URL:

   ```
   POST scheme://hostname:port/application/loggers/{name}
   ```

   The POST request requires a new log level parameter value that is provided in the request body:

   ```
   {
     "configuredLevel": "level"
   }
   ```
Where:

- level

is the new log level: OFF, ERROR, WARN, INFO, DEBUG, TRACE

Example:

Known Issues

API ML stops accepting connections after z/OS TCP/IP stack is recycled

Symptom:

When z/OS TCP/IP stack is restarted, it is possible that the internal services of API Mediation Layer (Gateway, Catalog, and Discovery Service) stop accepting all incoming connections, go into a continuous loop, and write a numerous error messages in the log.

Sample message:

The following message is a typical error message displayed in STDOUT:

```
    .at sun.nio.ch.ServerSocketChannelImpl.accept0(Native Method) ~.na:1.8.0.
    .at sun.nio.ch.ServerSocketChannelImpl.accept(ServerSocketChannelImpl.java:478) ~.na:1.8.0.
    .at sun.nio.ch.ServerSocketChannelImpl.accept(ServerSocketChannelImpl.java:287) ~.na:1.8.0.
    .at org.apache.tomcat.util.net.NioEndpoint$Acceptor.run(NioEndpoint.java:455) ~.tomcat-coyote-8.5.29.jar!/:8.5.29.
```

Solution:

Restart API Mediation Layer.

Tip: To prevent this issue from occurring, it is strongly recommended not to restart the TCP/IP stack while API ML is running.

SEC0002 error when logging in to API Catalog

SEC0002 error typically appears when users fail to log in to API Catalog. The following image shows the API Catalog login page with the SEC0002 error.
The error is caused by failed z/OSMF authentication. To determine the reason authentication failed, open the ZWESVSTC joblog and look for a message that contains ZosmfAuthenticationProvider. The following is an example of the message that contains ZosmfAuthenticationProvider:

```
2019-08-05 11:25:03.431 ERROR 5 --- .0.0-7552-exec-3.
    c.c.m.s.l.ZosmfAuthenticationProvider : Can not access z/OSMF service.
    Uri 'https://ABC12.slv.broadcom.net:1443' returned: I/O error on GET request for "https://ABC12.slv.broadcom.net:1443/zosmf/info": ...
```

Check the rest of the message, and identify the cause of the problem. The following list provides the possible reasons and solutions for the z/OSMF authentication issue:

- **Connection refused** on page 296
- Missing z/OSMF host name in subject alternative names
- Invalid z/OSMF host name in subject alternative names

**Connection refused**

In the following message, failure to connect to API Catalog occurs when connection is refused:

```
Connect to ABC12.slv.broadcom.net:1443 .ABC12.slv.broadcom.net/127.0.0.1. failed: EDC8128I Connection refused.; nested exception is
org.apache.http.conn.HttpHostConnectException:
```

The reason for the refused connection message is either invalid z/OSMF configuration or z/OSMF being unavailable. The preceding message indicates that z/OSMF is not on the 127.0.0.1:1443 interface.

**Solution:**
Configure z/OSMF

Make sure that z/OSMF is running and is on 127.0.0.1:1443 interface, and try to log in to API Catalog again. If you get the same error message, change z/OSMF configuration.

Follow these steps:
1. Locate the z/OSMF PARMLIB member IZUPRMxx.
   For example, locate IZUPRM00 member in SYS1.PARMLIB.
2. Change the current HOSTNAME configuration to HOSTNAME ('*').
3. Change the current HTTP_SSL_PORT configuration to HTTP_SSL_PORT('1443').
   Important! If you change the port in the z/OSMF configuration file, all your applications lose connection to z/OSMF.

For more information, see Syntax rules for IZUPRMxx.

If changing the z/OSMF configuration does not fix the issue, reconfigure Zowe.

Follow these steps:
1. Open .zowe_profile in the home directory of the user who installed Zowe.
2. Modify the value of the ZOWE_ZOSMF_PORT variable.
3. Reinstall Zowe.

Missing z/OSMF host name in subject alternative names

In following message, failure to connect to API Catalog is caused by a missing z/OSMF host name in the subject alternative names:

Certificate for <ABC12.slv.broadcom.net> doesn't match any of the subject alternative names: ..; nested exception is javax.net.ssl.SSLPeerUnverifiedException: Certificate for <ABC12.slv.broadcom.net> doesn't match any of the subject alternative names: ..

Solutions:

Fix the missing z/OSMF host name in subject alternative names using the following methods:

Note: Apply the insecure fix only if you use API Catalog for testing purposes.

- Secure fix
- Insecure fix on page 297

Secure fix

Follow these steps:
1. Obtain a valid certificate for z/OSMF and place it in the z/OSMF keyring. For more information, see Configure the z/OSMF Keyring and Certificate.
2. Re-create the Zowe keystore by deleting it and re-creating it. For more information, see Configuring Zowe certificates on page 102. The Zowe keystore directory is the value of the KEystore_DIRECTORY variable in the instance.env file in the instance directory that is used to launch Zowe. See Keystore configuration on page 106 for more information.

Insecure fix

Follow these steps:
1. Re-create the Zowe keystore by deleting it and re-creating it. For more information, see Configuring Zowe certificates on page 102. In the zowe-setup-certificates.env file that is used to generate the keystore, ensure that the property VERIFY_CERTIFICATES is set to FALSE.
Invalid z/OSMF host name in subject alternative names

In the following message, failure to connect to API Catalog is caused by an invalid z/OSMF host name in the subject alternative names:

Certificate for <ABC12.slv.broadcom.net> doesn't match any of the subject alternative names: [abc12.ca.com, abc12, localhost, abc12-slck, abc12-slck.ca.com, abc12-slck1, abc12-slck1.ca.com, abc12-slck2, abc12-slck2.ca.com, usilabc12, usilabc12.ca.com];

nested exception is javax.net.ssl.SSLPeerUnverifiedException: Certificate for <ABC12.slv.broadcom.net> doesn't match any of the subject alternative names: [abc12.ca.com, abc12, localhost, abc12-slck, abc12-slck.ca.com, abc12-slck1, abc12-slck1.ca.com, abc12-slck2, abc12-slck2.ca.com, usilabc12, usilabc12.ca.com]

Solutions:

Fix the invalid z/OSMF host name in the subject alternative names using the following methods:

- Request a new certificate on page 298
- Re-create the Zowe keystore on page 298

Request a new certificate

Request a new certificate that contains a valid z/OSMF host name in the subject alternative names.

Re-create the Zowe keystore

Re-create the Zowe keystore by deleting it and re-creating it. For more information, see Configuring Zowe certificates on page 102. The Zowe keystore directory is the value of the KEYSTORE_DIRECTORY variable in the instance.env file in the instance directory that is used to launch Zowe. See Keystore configuration on page 106.

API ML throws I/O error on GET request and cannot connect to other services

Symptom:

The API ML services are running but they are in DOWN state and not working properly. The following exceptions can be found in the log: java.net.UnknownHostException and java.net.NoRouteToHostException.

Sample message:

See the following message for full exceptions.

at org.springframework.web.client.RestTemplate.doExecute(RestTemplate.java:732) ~Spring-web-5.0.8.RELEASE.jar!/5.0.8.RELEASE

at org.springframework.web.client.RestTemplate.execute(RestTemplate.java:680) ~Spring-web-5.0.8.RELEASE.jar!/5.0.8.RELEASE

at org.springframework.web.client.RestTemplate.exchange(RestTemplate.java:600) ~Spring-web-5.0.8.RELEASE.jar!/5.0.8.RELEASE

at com.ca.mfaas.apicatalog.services.initialisation.InstanceRetrievalService.queryDiscoveryForInstances(InstanceRetrievalService.java:276) ~classes!/na
Solution:

The Zowe started task needs to run under the same user ID as z/OSMF (typically IZUSVR). This is stated in the installation documentation.

The hostname that is displayed in the details of the exception is a valid hostname. You can validate that the hostname is valid by using `ping` command on the same mainframe system. For example, `ping USILCA32.lvn.broadcom.net`. If it is valid, then the problem can be caused by insufficient privileges of your started task that is not allowed to do network access.

You can fix it by setting up the security environment as described in the Configure security environment switching on page 99.

Error Message Codes

The following error message codes may appear on logs or API responses. Use the following message code references and the corresponding reasons and actions to help troubleshoot issues.

**API mediation utility messages**

**ZWEAM000I**

%s has been started in %s seconds

**Reason:**

The service has been started

**Action:**

No action is needed

**API mediation common messages**

**ZWEAO102E**

Gateway not found yet, transform service cannot perform the request

**Reason:**

The Transform service was requested to transform a url, but the Gateway instance was not discovered.

**Action:**

Do not begin performing requests until the API Mediation Layer fully initializes after startup. Check that your Discovery service is running and that all services (especially the Gateway) are discovered correctly.

**ZWEAO104W**

GatewayInstanceInitializer has been stopped due to exception: %s

**Reason:**
An unexpected exception occurred while retrieving the Gateway service instance from the Discovery Service.

**Action:**
Check that both the service and the Gateway can register with Discovery. If the services are not registering, investigate the reason why. If no cause can be determined, create an issue.

**ZWEAO401E**
Unknown error in HTTPS configuration: '%s'

**Reason:**
An Unknown error occurred while setting up an HTTP client during service initialization, followed by a system exit.

**Action:**
Start the service again in debug mode to get a more descriptive message. This error indicates it is not a configuration issue.

**Common service core messages**

**ZWEAM100E**
Could not read properties from: '%s'

**Reason:**
The Build Info properties file is empty or null.

**Action:**
The jar file is not packaged correctly. Please submit an issue.

**ZWEAM101E**
I/O Error reading properties from: '%s' Details: '%s'

**Reason:**
I/O error reading META-INF/build-info.properties or META-INF/git.properties

**Action:**
The jar file is not packaged correctly. Please submit an issue.

**ZWEAM102E**
Internal error: Invalid message key '%s' is provided. Please create an issue with this message.

**Reason:**
Message service is requested to create message with an invalid key.

**Action:**
Create an issue with this message.

**ZWEAM103E**
Internal error: Invalid message text format. Please create an issue with this message.

**Reason:**
Message service is requested to create a message with an invalid text format.

**Action:**
Create an issue with this message.

**ZWEAM104E**
The endpoint you are looking for '%s' could not be located
Reason:
The endpoint you are looking for could not be located.

Action:
Verify that the URL of the endpoint you are trying to reach is correct.

ZWEAM400E
Error initializing SSL Context: ‘%s’

Reason:
An error occurred while initializing the SSL Context.

Action:
Refer to the specific message to identify the exact problem. Possible causes include:
• Incorrect security algorithm
• The keystore is invalid or corrupted
• The certificate is invalid or corrupted

ZWEAM500W
The service is not verifying the TLS/SSL certificates of the services

Reason:
This is a warning that the SSL Context will be created without verifying certificates.

Action:
Stop the service and set the verifySslCertificatesOfServices parameter to true. Then restart the service. Do not use this option in a production environment.

ZWEAM501W
Service is connecting to Discovery service using insecure HTTP protocol.

Reason:
The service is connecting to the Discovery Service using the non-secure HTTP protocol.

Action:
For production use, start the Discovery Service in HTTPS mode and configure the services accordingly.

ZWEAM502E
Error reading secret key: ‘%s’

Reason:
A key with the specified alias cannot be loaded from the keystore.

Action:
Ensure that the configured key is present, in the correct format, and not corrupt.

ZWEAM503E
Error reading secret key: ‘%s’

Reason:
Error reading secret key.

Action:
Refer to the specific message to identify the exact problem. Possible causes include:
• An incorrect security algorithm
• The keystore is invalid or corrupted
• The certificate is invalid or corrupted

ZWEAM504E
Error reading public key: '%s'

Reason:
Error reading secret key.

Action:
Refer to the specific message to identify the exact problem. Possible causes include:
• An incorrect security algorithm
• The keystore is invalid or corrupted
• The certificate is invalid or corrupted

ZWEAM505E
Error initializing SSL/TLS context: '%s'

Reason:
Error initializing SSL/TLS context.

Action:
Refer to the specific message to identify the exact problem. Possible causes include:
• An incorrect security algorithm
• The keystore is invalid or corrupted
• The certificate is invalid or corrupted

ZWEAM506E
Truststore Password configuration parameter is not defined

Reason:
Your truststore password was not set in the configuration.

Action:
Ensure that the parameter server.ssl.trustStorePassword contains the correct password for your truststore.

ZWEAM507E
Truststore configuration parameter is not defined but it is required

Reason:
The truststore usage is mandatory, but the truststore location is not provided.

Action:
If a truststore is required, define the truststore configuration parameter by editing the server.ssl.truststore,
server.ssl.truststorePassword and server.ssl.truststoreType parameters with valid data. If you do not require a
truststore, change the trustStoreRequired boolean parameter to false.

ZWEAM508E
Keystore not found, server.ssl.keyStore configuration parameter is not defined

Reason:
Your keystore path was not set in the configuration.

Action:
Ensure that the correct path to your keystore is contained in the parameter server.ssl.keyStore in the properties or yaml file of your service.

ZWEAM509E
Keystore password not found, server.ssl.keyStorePassword configuration parameter is not defined

Reason:
Your keystore password was not set in the configuration.

Action:
Ensure that the correct password to your keystore in the parameter server.ssl.keyStorePassword is contained in the properties or yaml file of your service.

ZWEAM510E
Invalid key alias '%s'

Reason:
The key alias was not found.

Action:
Ensure that the key alias provided for the key exists in the provided keystore.

ZWEAM511E
The certificate of the service accessed using URL '%s' is not trusted by the API Gateway: %s

Reason:
The Gateway does not trust the requested service and refuses to communicate with it. The certificate of the service is missing from the truststore of the API Mediation Layer.

Action:
Contact your administrator to verify API Mediation Layer truststore configuration.

ZWEAM600W
Invalid parameter in metadata: '%s'

Reason:
An invalid apiInfo parameter was found while parsing the service metadata.

Action:
Remove or fix the referenced metadata parameter.

ZWEAM700E
No response received within the allowed time: %s

Reason:
No response was received within the allowed time.

Action:
Verify that the URL you are trying to reach is correct and all services are running.

ZWEAM701E
The request to the URL '%s' has failed: %s caused by: %s

Reason:
Request failed because of an internal error.

Action:
Refer to specific exception details for troubleshooting. Create an issue with this message.

**Security common messages**

**ZWEAT100E**
Token is expired for URL '%s'

**Reason:**
The validity of the token is expired.

**Action:**
Obtain a new token by performing an authentication request.

**ZWEAT103E**
Could not write response: %s

**Reason:**
A message could not be written to the response

**Action:**
Please submit an issue with this message.

**ZWEAT601E**
z/OSMF service name not found. Set parameter apiml.security.auth.zosmfServiceId to your service ID.

**Reason:**
The parameter zosmfserviceId was not configured correctly and could not be validated.

**Action:**
Ensure that the parameter apiml.security.auth.zosmfServiceId is correctly entered with a valid zosmf service ID.

**Security client messages**

**ZWEAS100E**
Authentication exception: '%s' for URL '%s'

**Reason:**
A generic failure occurred while authenticating.

**Action:**
Refer to the specific message to troubleshoot.

**ZWEAS101E**
Authentication method '%s' is not supported for URL '%s'

**Reason:**
The HTTP request method is not supported for the URL.

**Action:**
Use the correct HTTP request method that is supported for the URL.

**ZWEAS103E**
API Gateway Service is not available by URL '%s' (API Gateway is required because it provides the authentication functionality)

**Reason:**
The security client cannot find a Gateway instance to perform authentication. The API Gateway is required because it provides the authentication functionality.

**Action:**

Check that both the service and Gateway are correctly registered in the Discovery service. Allow some time after the services are discovered for the information to propagate to individual services.

**ZWEAS104E**

Authentication service is not available by URL '%s'

**Reason:**

Authentication service is not available.

**Action:**

Make sure that authentication service is running and is accessible by the URL provided in the message.

**ZWEAS105E**

Authentication is required for URL '%s'

**Reason:**

Authentication is required.

**Action:**

Provide valid authentication.

**ZWEAS120E**

Invalid username or password for URL '%s'

**Reason:**

The username or password are invalid.

**Action:**

Provide a valid username and password.

**ZWEAS121E**

Authorization header is missing, or request body is missing or invalid for URL '%s'

**Reason:**

The authorization header is missing, or the request body is missing or invalid.

**Action:**

Provide valid authentication.

**ZWEAS130E**

Token is not valid for URL '%s'

**Reason:**

The token is not valid.

**Action:**

Provide a valid token.

**ZWEAS131E**

No authorization token provided for URL '%s'

**Reason:**
No authorization token is provided.

**Action:**
Provide a valid authorization token.

**ZAAS client messages**

**ZWEAS100E**
Token is expired for URL

**Reason:**
The application using the token kept it for longer than the expiration time

**Action:**
When this error occurs it is necessary to get a new JWT token.

**ZWEAS120E**
Invalid username or password

**Reason:**
Provided credentials weren't recognized

**Action:**
Try with different credentials

**ZWEAS121E**
Empty or null username or password values provided

**Reason:**
One of the credentials was null or empty

**Action:**
Try with full set of credentials

**ZWEAS122E**
Empty or null authorization header provided

**Reason:**
The authorization header was empty or null

**Action:**
Try again with valid authorization header

**ZWEAS170E**
An exception occurred while trying to get the token

**Reason:**
General exception. There are more information in the message

**Action:**
Log the message from the exception and then handle the exception based on the information provided there.

**ZWEAS400E**
Unable to generate PassTicket. Verify that the secured signon (PassTicket) function and application ID is configured properly by referring to Using PassTickets in the guide for your security provider

**Reason:**
Unable to generate PassTicket.

**Action:**
Verify that the secured signon (PassTicket) function and application ID is configured properly by referring to Using PassTickets in the guide for your security provider

**ZWEAS401E**
Token is not provided

**Reason:**
There was no JWT token provided for the generation of the PassTicket

**Action:**
Ensure that you are passing JWT token for PassTicket generation

**ZWEAS404E**
Gateway service is unavailable

**Reason:**
Gateway service doesn't respond.

**Action:**
Ensure that the Gateway service is up and that the path to the gateway service is properly set.

**ZWEAS417E**
The application name wasn't found

**Reason:**
The application id provided for the generation of the PassTicket wasn't recognized by security provider

**Action:**
Ensure that the security provider recognized the application id.

**ZWEAS500E**
There was no path to the trust store.

**Reason:**
The Zaas Client configuration didn't contain the path to the trust store

**Action:**
Ensure that the configuration contains the trustStorePath and that it points to valid trust store.

**ZWEAS501E**
There was no path to the key store.

**Reason:**
The Zaas Client configuration didn't contain the path to the key store

**Action:**
Ensure that the configuration contains the keyStorePath and that it points to valid key store.

**ZWEAS502E**
The configuration provided for SSL is invalid.

**Reason:**
The type of the keystore, truststore or the included keys/certs aren't considered valid
Action:
Ensure that the combination of the configuration is cryptographically valid.

**ZWEAS503E**
The SSL configuration contained invalid path.

**Reason:**
There was an invalid path to either trust store or keystore

**Action:**
Ensure that both provided paths are resolved to valid trust store and valid key store

**Discovery service messages**

**ZWEAD400E**
Cannot notify Gateway on '%s' about new instance '%s'

**Reason:**
The Discovery Service tried to notify the Gateway about instance update, but the REST call failed. The purpose of this call is to update the Gateway caches. The Gateway might be down or a network problem occurred.

**Action:**
Ensure there are no network issues and the Gateway was not restarted. If the problem reoccurs, contact Broadcom support.

**ZWEAD700W**
Static API definition directory '%s' is not a directory or does not exist

**Reason:**
One of the specified static API definition directories does not exist or is not a directory.

**Action:**
Review the static API definition directories and their setup. The static definition directories are specified as a launch parameter to a Discovery service jar. The property key is: `apiml.discovery.staticApiDefinitionsDirectories`

**ZWEAD701E**
Error loading static API definition file '%s'

**Reason:**
A problem occurred while reading (IO operation) of a specific static API definition file.

**Action:**
Ensure that the file data is not corrupted or incorrectly encoded.

**ZWEAD702W**
Unable to process static API definition data: '%s' - '%s'

**Reason:**
A problem occurred while parsing a static API definition file.

**Action:**
Review the mentioned static API definition file for errors. Refer to the specific log message to see what is the exact cause of the problem:

- Serviceld is not defined in the file '%s'. The instance will not be created. Make sure to specify the Serviceld.
• The `instanceBaseUrl` parameter of `%s` is not defined. The instance will not be created. Make sure to specify the `InstanceBaseUrl` property.

• The API Catalog UI tile ID `%s` is invalid. The service `%s` will not have an API Catalog UI tile. Specify the correct catalog title ID.

• One of the `instanceBaseUrl` of `%s` is not defined. The instance will not be created. Make sure to specify the `InstanceBaseUrl` property.

• The URL `%s` does not contain a hostname. The instance of `%s` will not be created. The specified URL is malformed. Make sure to specify valid URL.

• The URL `%s` does not contain a port number. The instance of `%s` will not be created.

• The specified URL is missing a port number. Make sure to specify a valid URL.

• The URL `%s` is malformed. The instance of `%s` will not be created: The specified URL is malformed. Make sure to specify a valid URL.

• The hostname of URL `%s` is unknown. The instance of `%s` will not be created: The specified hostname of the URL is invalid. Make sure to specify valid hostname.

• Invalid protocol. The specified protocol of the URL is invalid. Make sure to specify valid protocol.

• Additional service metadata of `%s` in processing file `%s` could not be created: `%s`

**ZWEAD703E**

A problem occurred during reading the static API definition directory: `%s`

**Reason:**

There are three possible causes of this error:

• The specified static API definition folder is empty.

• The definition does not denote a directory.

• An I/O error occurred while attempting to read the static API definition directory.

**Action:**

Review the static API definition directory definition and its contents on the storage. The static definition directories are specified as a parameter to launch a Discovery Service jar. The property key is: `apiml.discovery.staticApiDefinitionsDirectories`

**ZWEAD704E**

Gateway Service is not available so it cannot be notified about changes in Discovery Service

**Reason:**

Gateway Service is probably misconfigured or failed to start from another reason.

**Action:**

Review the log of Gateway Service and its configuration.

**Gateway service messages**

**ZWEAG700E**

No instance of the service '%s' found. Routing will not be available.

**Reason:**

The Gateway could not find an instance of the service from the Discovery Service.

**Action:**

Check that the service was successfully registered to the Discovery Service and wait for Spring Cloud to refresh the routes definitions

**ZWEAG701E**

Service '%s' does not allow encoded characters used in request path: '%s'.
**Reason:**
The request that was issued to the Gateway contains an encoded character in the URL path. The service that the request was addressing does not allow this pattern.

**Action:**
Contact the system administrator and ask to enable encoded characters in the service

**ZWEAG702E**
Gateway does not to allow encoded slashes in request: '%s'.

**Reason:**
The request that was issued to the Gateway contains an encoded slash in the URL path. Gateway configuration does not allow this encoding in the URL.

**Action:**
Contact the system administrator and ask to enable encoded slashes in the Gateway.

**ZWEAG704E**
Configuration error '%s' when trying to read jwt secret: %s

**Reason:**
A problem occurred while trying to read the jwt secret key from the keystore.

**Action:**
Review the mandatory fields used in the configuration such as the keystore location path, the keystore and key password, and the keystore type.

**ZWEAG705E**
Failed to load public or private key from key with alias '%s' in the keystore '%s'.

**Reason:**
Failed to load a public or private key from the keystore during JWT Token initialization.

**Action:**
Check that the key alias is specified and correct. Verify that the keys are present in the keystore.

**ZWEAG706E**
RequestContext not prepared for load balancing.

**Reason:**
Custom Ribbon load balancing is not in place before calling Ribbon.

**Action:**
Contact Broadcom support.

**ZWEAG707E**
The request to the URL '%s' has been aborted without retrying on another instance. Caused by: %s

**Reason:**
Request to server instance has failed and will not be retried on another instance.

**Action:**
Refer to Caused by details for troubleshooting.

**ZWEAG708E**
The request to the URL '%s' has failed after retrying on all known service instances. Caused by: %s
Reason:
Request to server instance could not be executed on any known service instance.

Action:
Verify status of the requested instance.

ZWEAG100E
Authentication exception: '%s' for URL '%s'

Reason:
A generic failure occurred during authentication.

Action:
Refer to specific authentication exception details for troubleshooting.

ZWEAG101E
Authentication method '%s' is not supported for URL '%s'

Reason:
The HTTP request method is not supported by the URL.

Action:
Use the correct HTTP request method supported by the URL.

ZWEAG102E
Token is not valid

Reason:
The JWT token is not valid.

Action:
Provide a valid token.

ZWEAG103E
Token is expired

Reason:
The JWT token has expired.

Action:
Obtain new token by performing an authentication request.

ZWEAG104E
Authentication service is not available at URL '%s'. Error returned: '%s'

Reason:
The authentication service is not available.

Action:
Make sure that the authentication service is running and is accessible by the URL provided in the message.

ZWEAG105E
Authentication is required for URL '%s'

Reason:
Authentication is required.
Action:
Provide valid authentication.

ZWEAG106W
Login endpoint is running in the dummy mode. Use credentials user/user to login. Do not use this option in the production environment.

Reason:
The authentication is running in dummy mode.

Action:
Do not use this option in the production environment.

ZWEAG107W
Incorrect value: apiml.security.auth.provider = '%s'. Authentication provider is not set correctly. Default 'zosmf' authentication provider is used.

Reason:
An incorrect value of the apiml.security.auth.provider parameter is set in the configuration.

Action:
Ensure that the value of apiml.security.auth.provider is set either to 'dummy' if you want to use dummy mode, or to 'zosmf' if you want to use the z/OSMF authentication provider.

ZWEAG108E
z/OSMF instance '%s' not found or incorrectly configured.

Reason:
The Gateway could not find the z/OSMF instance from the Discovery Service.

Action:
Ensure that the z/OSMF instance is configured correctly and that it is successfully registered to the Discovery Service.

ZWEAG109E
z/OSMF response does not contain field '%s'.

Reason:
The z/OSMF domain cannot be read.

Action:
Review the z/OSMF domain value contained in the response received from the 'zosmf/info' REST endpoint.

ZWEAG110E
Error parsing z/OSMF response. Error returned: '%s'

Reason:
An error occurred while parsing the z/OSMF JSON response.

Action:
Check the JSON response received from the 'zosmf/info' REST endpoint.

ZWEAG120E
Invalid username or password for URL '%s'

Reason:
The username or password are invalid.

**Action:**

Provide a valid username and password.

**ZWEAG121E**

Authorization header is missing, or request body is missing or invalid for URL ‘%s’

**Reason:**

The authorization header is missing, or the request body is missing or invalid.

**Action:**

Provide valid authentication.

**ZWEAG130E**

Token is not valid for URL ‘%s’

**Reason:**

The token is not valid.

**Action:**

Provide a valid token.

**ZWEAG131E**

No authorization token provided for URL ‘%s’

**Reason:**

No authorization token is provided.

**Action:**

Provide a valid authorization token.

**ZWEAG140E**

The 'applicationName' parameter name is missing.

**Reason:**

The application name is not provided.

**Action:**

Provide the 'applicationName' parameter.

**ZWEAG141E**

The generation of the PassTicket failed. Reason: %s

**Reason:**

An error occurred in the SAF Auth Service. Review the reason in the error message.

**Action:**

Supply a valid user and application name, and check that corresponding permissions have been set up.

**API Catalog messages**

**ZWEAC100W**

Could not retrieve all service info from discovery -- %s -- %s -- %s

**Reason:**

The response from The Discovery Service about the registered instances returned an error or empty body.
Action:
Make sure the Discovery Service is up and running. If the http response error code refers to a security issue, check that both the Discovery Service and Catalog are running with the https scheme and that security is configured properly.

**ZWEAC101E**
Could not parse service info from discovery -- %s

**Reason:**
The response from the Discovery Service about the registered instances could not be parsed to extract applications.

**Action:**
Run debug mode and look at the Discovery Service potential issues while creating a response. If the Discovery Service does not indicate any error, create an issue.

**ZWEAC102E**
Could not retrieve containers. Status: %s

**Reason:**
One or more containers could not be retrieved.

**Action:**
Check the status of the message for more information and the health of the Discovery Service.

**ZWEAC103E**
API Documentation not retrieved, %s

**Reason:**
API documentation was not found.

**Action:**
Make sure the service documentation is configured correctly.

**ZWEAC104E**
Could not retrieve container statuses, %s

**Reason:**
One or more containers statuses could not be retrieved.

**Action:**
Check the status of the message for more information and the health of Discovery Service.

**ZWEAC700E**
Failed to update cache with discovered services: '%s'

**Reason:**
Cache could not be updated.

**Action:**
Check the status of the Discovery Service.

**ZWEAC701W**
API Catalog Instance not retrieved from Discovery service

**Reason:**
An error occurred while fetching containers information.
**Action:**
The jar file is not packaged correctly. Please submit an issue.

**ZWEAC702E**
An unexpected exception occurred when trying to retrieve an API Catalog instance from the Discovery Service: %s

**Reason:**
An unexpected error occurred during API Catalog initialization. The API Catalog was trying to locate an instance of itself in the Discovery Service.

**Action:**
Review the specific message for more information. Verify if the Discovery Service and service registration work as expected.

**ZWEAC703E**
Failed to initialize API Catalog with discovered services

**Reason:**
The API Catalog could not initialize running services after several retries.

**Action:**
Ensure services are started and discovered properly.

**ZWEAC704E**
ApiDoc retrieval problem for '%s' service. %s

**Reason:**
ApiDoc for service could not be retrieved.

**Action:**
Verify that the service provides a valid ApiDoc.

**ZWEAC705W**
The home page url for service %s was not transformed. %s

**Reason:**
The home page url for service was not transformed. The original url will be used.

**Action:**
Refer to the specific printed message. Possible causes include:

- The Gateway was not found. Transform service cannot perform the request. Wait for the Gateway to be discovered.
- The URI ... is not valid. Ensure the service is providing a valid url.
- Not able to select a route for url ... of the service ... Original url is used. If this is a problem, check the routing metadata of the service.
- The path ... of the service URL ... is not valid. Ensure the service is providing the correct path.

**ZWEAC706E**
Service not located, %s

**Reason:**
The service could not be found.

**Action:**
Check if the service is up and registered. If it is not registered, review the onboarding guide to ensure that all steps were completed.

Zowe Application Framework

Troubleshooting Zowe Application Framework

The following topics contain information that can help you troubleshoot problems when you encounter unexpected behavior installing and using Zowe™ Application Framework which includes the Zowe Desktop.

Most of the solutions below identify issues by referring to the Gathering information to troubleshoot Zowe Application Framework on page 319. To identify and resolve issues, you should be familiar with their names and locations.

The Zowe Application Framework manages issues in GitHub. When you troubleshoot a problem, you can check whether a GitHub issue (open or closed) that covers the problem already exists. For a list of issues, see the zlux repo.

Desktop apps fail to load

Symptom:
When you open apps in the Zowe desktop, a page is displayed with the message "The plugin failed to load."

Solution:
This problem might occur when you use Node.js v8.16.1, which performs auto-encoding in a way that breaks Zowe apps. See https://github.com/ibmruntimes/node/issues/142 for details.

To solve the problem, use a different version of Node.js v8, such as v8.17.0, or use Node.js v12. You can obtain them from the Node.js marketplace. Download the ibm-trial-node-v8.17.0-os390-s390x.pax.z file.

NODEJSAPP disables immediately

Symptom:
You receive the message CEE5207E The signal SIGABRT was received in stderr.

Solution:
You might have reached the limit for shared message queues on your LPAR. When Node.js applications are terminated by a SIGKILL signal, shared message queues might not be deallocated. For more information, see the If the NODEJSAPP disables immediately section in the Troubleshooting Node.js applications topic on IBM Knowledge Center.

Cannot log in to the Zowe Desktop

Symptom:
When you attempt to log in to the Zowe Desktop, you receive the following error message that is displayed beneath the Username and Password fields.

```
Authentication failed for 1 types: Types: ["zss"]
```

Solution:
For the Zowe Desktop to work, the node server that runs under the ZWESVSTC started task must be able to make cross memory calls to the ZWESIS01 load module running under the ZWESISTC started task. If this communication fails, you see the authentication error.

There are two known problems that might cause this error. The Zowe architecture on page 13 shows a path from the Zowe Desktop ZLUX server to the zssServer (across the default port 8542) which then connects to the ZWESIS01 started task using cross memory communication. One of those two connections (ZLUX to zssServer, or zssServer to X-MEM) likely failed.
• **ZSS server unable to communicate with X-MEM** on page 317
• **ZLUX unable to communicate with zssServer** on page 317

### ZSS server unable to communicate with X-MEM

1. Open the log file `$INSTANCE_DIR/logs/zssServer-yyyy-mm-dd-hh-ss.log`. This file is created each time ZWESVSTC is started and only the last five files are kept.
2. Look for the message that starts with **ZIS status**.
   - If the communication works, the message includes **Ok**. For example:
     ```
     ZIS status - Ok (name='ZWESIS_STD', cmsRC=0, description='Ok')
     ```
   If the communication works, the problem is likely that the ZLUX server is unable to communicate to the zssServer. For more information, see **ZLUX unable to communicate with zssServer** on page 317.
   - If the communication is not working, the message includes **Failure**. For example:
     ```
     ZIS status - Failure (name='ZWESIS_STD', cmsRC=39, description='Cross-memory call ABENDED')
     ```
   In this case, check that the ZWESISSTD started task is running. If not, start it. Also, search the log for problems, such as statements indicating that the server was unable to find the load module.
   - If the problem cannot be easily fixed (such as the ZWESISSTD task not running), then it is likely that the cross memory server setup and configuration did not complete successfully. To set up and configure the cross memory server, follow steps as described in the topic **Installing and configuring the Zowe cross memory server (ZWESVSTC)** on page 108.
   - If there is an authorization problem, the message might include **Permission Denied**. For example:
     ```
     ZIS status - Failure (name='ZWESIS_STD', cmsRC=33, description='Permission denied')
     ```
     Check that the user ID of the ZWESVSTC started task is authorized to access the load module. Only authorized code can call ZWESIS01 because it is an APF-authorized load module.

### Note:
If you are using RACF security manager, a common reason for seeing **Permission Denied** is that the user running the started task ZWESVSTC (typically ZWESVUSR) does not have READ access to the FACILITY class ZWES.IS.

If the message includes the following text, the configuration of the Application Framework server may be incomplete:

```
ZIS status - Failure read failed ret code 1121 reason 0x76650446
```

If you are using AT/TLS, then the "attls" : true statement might be missing from the `zluxserver.json` file. For more information, see **Configuring ZSS for HTTPS** on page 125.

### ZLUX unable to communicate with zssServer

On the **Zowe architecture** on page 13, there is a communication between ZLUX which is a Node.js runtime serving the Zowe desktop web pages to the user's browser, and the zssServer running on port 8542. If this communication is failing, then you will be unable to log in to the desktop.

Follow these steps:
1. Open the log file `$INSTANCE_DIR/logs/appServer-yyyy-mm-dd-hh-ss.log`. This file is created each time ZWESVSTC is started and only the last five files are kept.
2. Look for the message that starts with `GetAddrInfoReqWrap.onlookup` and the log messages below.

```
yyyy-mm-dd hh:mm:ss.ms <ZWED:16842977> ZWESVUSR INFO (_zsf.apiml,apiml.
yyyy-mm-dd hh:mm:ss.ms <ZWED:16842977> ZWESVUSR INFO (_zsf.auth,weauth
yyyy-mm-dd hh:mm:ss.ms <ZWED:16842977> ZWESVUSR WARN (_zsf.proxy,proxy.
```
3. Map localhost to port 127.0.0.1.
   Create an entry in the file /etc/hosts that contains the line

   127.0.0.1 localhost

4. Restart the ZWESVSTC address space.

Server startup problem ret=1115

Symptom: When ZWESVSTC is restarted, the following message is returned in the output of the ZSS server log file, $INSTANCE_DIR/logs/zssServer-yyyy-mm-dd-hh-ss.log:

server startup problem ret=1115

Solution: This message means that some other process is already listening on port 7542, either at address 127.0.0.1 (localhost) or at 0.0.0.0 (all addresses). This prevents the ZSS server from starting.

One possibility is that a previously running ZSS server did not shut down correctly, and either the operating system has not released the socket after the ZSS server shut down, or the ZSS server is still running.

Application plug-in not in Zowe Desktop

Symptom: An application plug-in is not appearing in the Zowe Desktop.

Solution: To check whether the plug-in loaded successfully, enter the following URL in a browser to display all successfully loaded Zowe plug-ins:

https://my.mainframe.com:8544/plugins?type=application

You can also search the Gathering information to troubleshoot Zowe Application Framework on page 319 for the plug-in identifier, for example org.zowe.sample.app. If the plug-in loaded successfully, you will find the following message:

If the plug-in did not load successfully, you will find the following message:

If the identifier is not in the logs, make sure the plug-in's locator file is in the /zlux-app-server/deploy/instance/ZLUX/plugins/ directory. The plug-in locator is a .json file, usually with same name as the identifier, for example org.zowe.sampleapp.json. Open the file and make sure that the path that is defined with the pluginLocation attribute is correct. If the path is relative, make sure it is relative to the zlux-app-server/bin directory.

For more information on loading plug-ins to the Desktop, see Adding Your App to the Desktop.

Error: You must specify MVD_DESKTOP_DIR in your environment

Symptom:

A plug-in that is built in your local environment using npm run start or npm run build failed with an error message about a missing MVD_DESKTOP_DIR environment variable.
Solution: Add the Zowe Desktop directory path to the MVD_DESKTOP_DIR environment variable. To specify the path, run the following commands in your Windows console or Linux bash shell:

- **Windows**
  ```bash
  export MVD_DESKTOP_DIR=<zlux-root-dir>/zlux-app-manager/virtual-desktop
  ```

- **Mac Os/Linux**
  ```bash
  set MVD_DESKTOP_DIR=<zlux-root-dir>/zlux-app-manager/virtual-desktop
  ```

**Error: Problem making eureka request**

**Symptom:**
The Zowe started task ZWESVSTC log contains error messages reporting problems connecting

```javascript
Problem making eureka request { Error: connect ECONNREFUSED 10.1.1.2:7553
at TCPConnectWrap.afterConnect [as oncomplete] (net.js:1195:14)
errno: 'ECONNREFUSED',
  code: 'ECONNREFUSED',
syscall: 'connect',
address: '10.1.1.2',
port: 7553 }
```

Solution: You can ignore these messages. These messages are timing-related where different Eureka servers come up, try to connect to each other, and warn that the endpoint they are trying to perform a handshake with is not available. When all of the Eureka services have started, these errors will stop being logged.

**Gathering information to troubleshoot Zowe Application Framework**

Gather the following information to troubleshoot Zowe™ Application Framework issues:

- **z/OS release level**
- **Zowe version and release level** on page 319
- **Zowe application configuration** on page 320
- **Zowe Application Server ports** on page 320
- **Log output from the Zowe Application Server** on page 320
- **Error message codes** on page 321
- **Javascript console output** on page 321
- **Screen captures** on page 321
- **Other relevant information** on page 321

**z/OS release level**

To find the z/OS release level, issue the following command in SDSF:

```bash
/D IPLINFO
```

Check the output for the release level, for example:

```bash
RELEASE z/OS 02.02.00
```

**Zowe version and release level**

```bash
cd <zowe-installation-directory>
cat manifest.json
```

Output:
Zowe application configuration

Configuration file helps customize the Zowe app server, and is important to look at while you troubleshoot.

```
# navigate to zowe installation folder
cd <zowe-installation-folder>

# navigate to server configuration folder
cd zlux-app-server/deploy/instance/ZLUX/serverConfig

# display config
cat zluxserver.json
```

Read more about the Zowe app server Zowe Application Framework configuration on page 120 in the Zowe User Guide.

Zowe Application Server ports

```
# navigate to zowe installation folder
cd <zowe-installation-folder>

# navigate to install log directory
cd install_log

# list file by most recent first
ls -lt

# pick latest file
cat 2019-05-02-17-13-09.log | grep ZOWE_ZLUX_SERVER_HTTPS_PORT
cat 2019-05-02-17-13-09.log | grep ZOWE_ZSS_SERVER_PORT
```

Log output from the Zowe Application Server

There are two major components of Zowe application server: ZLUX and ZSS. They log to different files.
The default location for logs for both zlux and zss is folder zlux-app-server/log. You can customize the log location by using the environment variable.

```
env | grep ZLUX_NODE_LOG_DIR
env | grep ZSS_LOG_DIR
```

Read more about controlling the log location [Controlling the logging location](#) on page 135.

```
# navigate to zowe installation folder
cd <zowe-installation-folder>

# navigate to logs default location or custom location as described above
cd zlux-app-server/log

# custom log location can be found using environment variable

# list file by most recent first
ls -lt
```

**Output:**

List of files by most recent timestamp for both nodeServer as well ZSS.

```
nodeServer-<yyyy-mm-dd-hh-mm>.log
zssServer-<yyyy-mm-dd-hh-mm>.log
```

**Error message codes**

It is advisable to look into log files for capturing error codes.

**Javascript console output**

Web Developer toolkit is accessible by pressing F12.

Read more about it [here](#).

**Screen captures**

If possible, add a screen capture of the issue.

**Other relevant information**

```
node -v
```

```
npm – v6.4 minimum
```

```
npm -v
```

Java – v8 minimum

```
java -version
```

**Raising a Zowe Application Framework issue on GitHub**

When necessary, you can raise GitHub issues against the Zowe™ zlux core repository [here](#). It is suggested that you use either the bug or enhancement template.

For issues with particular applications, such as Code Editor or JES Explorer, create the issue in the application’s project.
Raising a bug report

Please provide as much of the information listed on Troubleshooting Zowe Application Framework on page 316 as possible. Anyone working on the issue might need to request this and other information if it is not supplied initially. A description of the error and how it can be reproduced is the most important information.

Raising an enhancement report

Enhancement reports are just as important to the Zowe project as bug reports. Enhancement reports should be clear and detailed requirements for a potential enhancement.

Troubleshooting z/OS Services

The following topics contain information that can help you troubleshoot problems when you encounter unexpected behavior installing and using Zowe™ z/OS Services.

Unable to generate unique CeaTso APPTAG

Symptom:

When you request a Zowe data set or z/OS Files API, you receive a response code 500 - 'Internal Server Error', with a message "Unable to generate unique CeaTso APPTAG".

Solution:

Check z/OSMF settings of REST API of file. You must define RESTAPI_FILE in IZUPRMxx by the following statement:

RESTAPI_FILE ACCT(IZUACCT) REGION(32768) PROC(IZUFPROC)

The default IZUFPROC can be found in SYS1.PPROCLIB. And the proper authorization is needed to get IZUFPROC work successfully.

z/OS Services are unavailable

If the z/OS Services are unavailable, take the following corrective actions.
• Ensure that the z/OSMF REST API services are working. Check the z/OSMF IZUSVR1 task output for errors and confirm that the z/OSMF RESTFILES services are started successfully. If no errors occur, you can see the following message in the IZUSVR1 job output:

```
CWWKZ0001I: Application IzuManagementFacilityRestFiles started in n.nnn seconds.
```

To test z/OSMF REST APIs you can run curl scripts from your workstation.

```
```

where the `securezosmfport` is 443 by default. You can verify the port number by checking the `izu.https.port` variable assignment in the z/OSMF bootstrap.properties file.

If z/OSMF returns jobs correctly, you can test whether it is able to returns files by using the following curl scripts:

```
```

If the restfiles curl statement returns a TSO SERVLET EXCEPTION error, check that the the z/OSMF installation step of creating a valid IZUFPROC procedure in your system PROCLIB has been completed. For more information, see the z/OSMF Configuration Guide.

The IZUFPROC member resides in your system PROCLIB, which is similar to the following sample:

```
//IZUFPROC PROC ROOT='/usr/lpp/zosmf' /* zOSMF INSTALL ROOT */
//IZUFPROC EXECPGM=IKJEFT01,DYNAMNBR=200
//SYSEXEC DD DISP=SHR,DSN=ISP.SISPEXEC
// DD DISP=SHR,DSN=SYS1.SBPXEXEC
//SYSPROC DD DISP=SHR,DSN=ISP.SISPCIBL
// DD DISP=SHR,DSN=SYS1.SBPXEXEC
//ISPLLIB DD DISP=SHR,DSN=SYS1.SIEALNKE
//ISPLLIB DD DISP=SHR,DSN=ISP.SISPPENU
//ISPTLIB DD REC FM=FB, LRE CL=80, SPACE=(TRK, (1,0,1))
// DD DISP=SHR,DSN=ISP.SISPTENU
//ISPSLIB DD DISP=SHR,DSN=ISP.SISPENU
//ISPMLIB DD DISP=SHR,DSN=ISP.SISPMENU
//ISPPROF DD DISP=NEW,UNIT=SYSDA,SPACE=(TRK, (15,15,5)),
// DCB=(RECFM=FB, LRE CL=80, BLK SIZE=3120)
//IZUSRVMPP DD PATH='&ROOT./defaults/izurf.tsoservlet.mapping.json'
//SYSOUT DD SYSOUT=H
//CEEDUMP DD SYSOUT=H
//SYSUDUMP DD SYSOUT=H
//
```

Note: You might need to change paths and data sets names to match your installation.

A known issue and workaround for RESTFILES API can be found at TSO SERVLET EXCEPTION ATTEMPTING TO USE RESTFILE INTERFACE.

• Check your system console log for related error messages and respond to them.
Troubleshooting Zowe CLI

Problem
Zowe™ CLI is experiencing a problem. You need to collect information that will help you resolve the issue.

Environment
These instructions apply to Zowe CLI installed on Windows, Mac OS X, and Linux systems as a standalone installation via a Zowe download or an NPM registry.

Before reaching out for support
1. Is there already a GitHub issue (open or closed) that covers the problem? Check CLI Issues.
2. Review the current list of Known Zowe CLI issues on page 327 in documentation. Also try searching using the Zowe Docs search bar.

Resolving the problem
Collect the following information to help diagnose the issue:

- Zowe CLI version installed.
- List of plug-ins installed and their version numbers.
- Node.js and NPM versions installed.
- List of environment variables in use.

For instructions on how to collect the information, see Gathering information to troubleshoot Zowe CLI on page 324.

The following information is also useful to collect:

- If you are experiencing HTTP errors, see z/OSMF troubleshooting on page 327 for information to collect.
- Is the CLI part of another Node application, such as VSCode, or is it a general installation?
- Which operating system version are you running on?
- What shell/terminal are you using (bash, cmd, powershell, etc...)?
- Which queue managers are you trying to administer, and on what systems are they located?
- Are the relevant API endpoints online and valid?

Gathering information to troubleshoot Zowe CLI

Follow these instructions to gather specific pieces of information to help troubleshoot Zowe™ CLI issues.

[ ]

Identify the currently installed CLI version

Issue the following command:

```
zowe -V
```

The exact Zowe CLI version may vary depending upon if the @latest or @zowe-v1-lts, or @lts-incremental version is installed.

For the @zowe-v1-lts and the @latest (forward-development) version tags:

```
npmlist -g @zowe/cli
```
For the @lts-incremental version tag:

```
npm list -g @brightside/core
```

More information regarding versioning conventions for Zowe CLI and plug-ins is located in Versioning Guidelines.

**Identify the currently installed versions of plug-ins**

Issue the following command:

```
zowe plugins list
```

The output describes version and the registry information.

**Environment variables**

The following settings are configurable via environment variables:

**Log levels**

Environment variables are available to specify logging level and the CLI home directory.

**Important!** Setting the log level to TRACE or ALL might result in "sensitive" data being logged. For example, command line arguments will be logged when TRACE is set.

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Description</th>
<th>Values</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZOWE_APP_LOG_LEVEL</td>
<td>Zowe CLI logging level</td>
<td>Log4JS log levels (OFF, TRACE, DEBUG, INFO, WARN, ERROR, FATAL)</td>
<td>DEBUG</td>
</tr>
<tr>
<td>ZOWE_IMPERATIVE_LOG_LEVEL</td>
<td>Imperative CLI Framework logging level</td>
<td>Log4JS log levels (OFF, TRACE, DEBUG, INFO, WARN, ERROR, FATAL)</td>
<td>DEBUG</td>
</tr>
</tbody>
</table>

**Home directory**

You can set the location on your computer for the Zowe CLI home directory, which contains log files, profiles, and plug-ins for the product.

**Tip!** The default .zowe folder is created when you issue your first Zowe CLI command. If you change the location of the folder, you must reinstall plug-ins and recreate or move profiles and log files that you want to retain. In some cases, you might want to maintain a different set of profiles in multiple folders, then switch between them using the environment variable.

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Description</th>
<th>Values</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZOWE_CLI_HOME</td>
<td>Zowe CLI home directory location</td>
<td>Any valid path on your computer</td>
<td>C:\Users&lt;username&gt;.zowe</td>
</tr>
</tbody>
</table>

The values for these variables can be echo'd.

Location of logs

There are two sets of logs to be aware of:

- Imperative CLI Framework log, which generally contains installation and configuration information.
- Zowe CLI log, which contains information about interaction between CLI and the server endpoints.

Analyze these logs for any information relevant to your issue.

Profile configuration

The **profiles** folder stores connection information.

**Important!** The profile directory might contain "sensitive" information, such as your mainframe password. You should obfuscate any sensitive references before providing configuration files.

Node.js and npm

Zowe CLI should be compatible with Node.js v8 and greater.

To gather Node.js and npm versions, use the following:

```
node --version
npm --version
```

npm configuration

If you are having trouble installing Zowe CLI from an npm registry, gather your npm configuration to help identify issues with registry settings, global install paths, proxy settings, etc...

```
npm config ls -1
```
**npm log files**

In case of errors, npm creates log files in the `npm_cache\_logs` location. To get the `npm_cache` location for a specific OS, run the following command:

```
npn config get cache
```

By default, npm keeps only 10 log files, but sometimes more are needed. Increase the log count by issuing the following command:

```
npn config set logs-max 50
```

This command increases the log count to 50, so that more log files will be stored on the system. Now you can run tests multiple times and not lose the log files. The logs can be passed to Support for analysis.

As the log files are created only when an npm command fails, but you are interested to see what is executed, you can increase the log level of npm. Issue the following command:

```
npn config set loglevel verbose
```

- With this change, you can see all actions taken by npm on the stdout. If the command is successful, it still does not generate a log file.
- The available log levels are: "silent", "error", "warn", "notice", "http", "timing", "info", "verbose", "silly", and "notice". "Notice" is the default.
- Alternatively, you can pass `--loglevel verbose` on the command line, but this only works with npm related commands. By setting log level in the config, it also works when you issue some `zowe` commands that use npm (for example, `zowe plugins install @zowe/cics`).

**z/OSMF troubleshooting**

The core command groups use the z/OSMF REST APIs which can experience any number of problems.

If you encounter HTTP 500 errors with the CLI, consider gathering the following information:

1. The IZU* (IZUSVR and IZUANG) joblogs (z/OSMF server)
2. z/OSMF USS logs (default location: /global/zosmf/data/logs - but may change depending on installation)

If you encounter HTTP 401 errors with the CLI, consider gathering the following information:

1. Any security violations for the TSO user in SYSLOG

**Alternate methods**

At times, it may be beneficial to test z/OSMF outside of the CLI. You can use the CLI tool `curl` or a REST tool such as "Postman" to isolate areas where the problem might be occurring (CLI configuration, server-side, etc.).

Example `curl` command to GET `/zosmf/info`:

```
```

**Known Zowe CLI issues**

The following topics contain information that can help you troubleshoot problems when you encounter unexpected behavior installing and using Zowe™ CLI.

**EACCESS error when issuing npm install command**

Valid on Windows, Mac, or Linux

Symptom:
An EACCESS error is returned when you issue the `npm install -g` command to install a package from Zowe.org or npm.

Solution:
To resolve the issue, follow the steps described in Resolving EACCESS permissions errors when installing packages globally in the npm documentation.

**Command not found message displays when issuing `npm install` commands**
Valid on all supported platforms

Symptom:
When you issue NPM commands to install the CLI, the message `command not found` displays. The message indicates that Node.js and NPM are not installed on your computer, or that PATH does not contain the correct path to the NodeJS folder.

Solution:
To correct this behavior, verify the following:

- Node.js and NPM are installed.
- PATH contains the correct path to the NodeJS folder.

More Information: System requirements on page 48

**`npm install -g` Command Fails Due to an EPERM Error**
Valid on Windows

Symptom:
This behavior is due to a problem with Node Package Manager (npm). There is an open issue on the npm GitHub repository to fix the defect.

Solution:
If you encounter this problem, some users report that repeatedly attempting to install Zowe CLI yields success. Some users also report success using the following workarounds:

- Issue the `npm cache clean` command.
- Uninstall and reinstall Zowe CLI. For more information, see Installing Zowe CLI on page 116.
- Add the `--no-optional` flag to the end of the `npm install` command.

**Sudo syntax required to complete some installations**
Valid on Linux and macOS

Symptom:
The installation fails on Linux or macOS.

Solution:
Depending on how you configured Node.js on Linux or macOS, you might need to add the prefix `sudo` before the `npm install -g` command or the `npm uninstall -g` command. This step gives Node.js write access to the installation directory.

**`npm install -g` command fails due to `npm ERR! Cannot read property 'pause' of undefined` error**
Valid on Windows or Linux

Symptom:
You receive the error message `npm ERR! Cannot read property 'pause' of undefined` when you attempt to install the product.
Solution:
This behavior is due to a problem with Node Package Manager (npm). If you encounter this problem, revert to a previous version of npm that does not contain this defect. To revert to a previous version of npm, issue the following command:

```
npm install npm@5.3.0 -g
```

**Node.js commands do not respond as expected**

**Valid on Windows or Linux**

**Symptom:**
You attempt to issue node.js commands and you do not receive the expected output.

**Solution:**
There might be a program that is named node on your path. The Node.js installer automatically adds a program that is named node to your path. When there are pre-existing programs that are named node on your computer, the program that appears first in the path is used. To correct this behavior, change the order of the programs in the path so that Node.js appears first.

**Installation fails on Oracle Linux 6**

**Valid on Oracle Linux 6**

**Symptom:**
You receive error messages when you attempt to install the product on an Oracle Linux 6 operating system.

**Solution:**
Install the product on Oracle Linux 7 or another Linux or Windows OS. Zowe CLI is not compatible with Oracle Linux 6.

**Raising a CLI issue on GitHub**

When necessary, you can raise GitHub issues against the Zowe™ CLI repository here. It is suggested that you use either the bug or enhancement template.

**Raising a bug report**
Please provide as much of the information listed on Troubleshooting Zowe CLI on page 324 as is reasonable. Anyone working on the issue might need to request this and other information if it is not supplied initially. A description of the error and how it can be reproduced is the most important information.

**Raising an enhancement report**
Enhancement reports are just as important to the Zowe project as bug reports. Enhancement reports should be clear and detailed requirements for a potential enhancement.
